Herr Baumann has entered into a mathematical discussion of the method of determining the greatest actual net load which may be carried under given circumstances, and also the minimum weight of the rope in order to be able to hoist without danger. We must refer to the original for the details of these calculations, and will in the following merely give the results. Assuming the dead load to be D, consisting of the weight of the cage and the cars, and L the live load, being either net quantity of rock hoisted or the weight of the men in the cage, then the depth at which it is possible to begin to apply the Koepe system, when the rope grasps only one half the circumference of the sheave is as follows, for different ratios in the proportion of live to dead load.

For Wire Rope on Cast-Iron Sheaves.

$\frac{D}{L}$	Steel Rope. Factor of safety 10.	Iron Rope. Factor of safety 8.	Iron Rope. Factor of safety 10.
2	192 meters.	128 meters.	96 meters.
1·9	224 "	150 "	112 "
1·8	256 "	169 "	128 "
1·7	288 "	192 "	144 "
1·6	320 "	214 "	160 "
1·5	353 "	235 "	176 "

For Wire Rope Running on Oak.

$\frac{D}{L}$	Steel Rope. Factor of safety 10.	Iron Rope. Factor of safety 8.	Iron Rope. Factor of safety 10.
1·8	23 meters.	15 meters.	12 meters.
1·7	63 "	42 "	32 "
1·6	104 "	69 "	52 "
1·5	144 "	96 "	72 "

By using guide-rollers, the rope can be made to grasp a greater proportion of the circumference of the sheave, and hoisting is safe then at much smaller depths. Making it, for instance, so that the angle formed by the center and the two points where the rope leaves the sheave is 225 degrees, the following figures are obtained:

$\frac{D}{L}$	Steel Rope. Factor of safety 10	Iron Rope. Factor of safety 8.	Iron Rope. Factor of safety 10.
1·8	32 meters.	21 meters.	16 meters.
1·7	72 "	48 "	36 "
1·6	112 "	75 "	56 "
1·5	152 "	102 "	76 "

In well-constructed hoisting plants, the ratio between dead and live load is rarely more than 1·5, and, as the figures above show, even for so low a ratio it is possible to use the Koepe system without danger of sliding. The use of flat ropes is particularly recommended, and by attaching the cage by a clutch, no trouble is experienced in making the necessary changes for hoisting from different levels.

THE RAILROAD EXPOSITION AT CHICAGO.

Special Correspondence of the Engineering and Mining Journal.

The National Exposition of Railway Appliances opened at Chicago on the 24th of May, and will continue until the 23d of June. The building, under which are amassed many thousand exhibits, covers several acres of ground, every inch of available space having been assigned. At this writing, the Exhibition is fairly under way, some delay being caused by the multiplicity of exhibits and the natural commotion of a large undertaking. The management deserves credit for the general excellence and ability evinced in the Exhibition as a whole. It has been no small labor to accumulate such an unique exhibition of railroad appliances. The Exhibition affords to the mechanic subjects for study which will enable him to trace minutely the course of development which has brought the modern railroad to its present degree of perfection. The impress of inventive genius is seen on all sides, and although it would seem almost impossible to improve upon the character of the present established features, the restless men who lead progress are now at work to supplant steam by utilizing the electric fluid as a motive power. The best results do not seem beyond reach, as exemplified in the half-mile electric railroad now in operation at this Exhibition.

It would fill more space than your JOURNAL commands in one issue, to dwell upon the separate exhibits, which embrace every conceivable adjunct known in operating a railroad, to say nothing of those recently brought before the notice of visitors and not yet utilized. It is doubtful whether a similar exhibition could be collected, at least in the present generation, as the resources of many countries have been drawn upon to contribute to the success of this one. That it is now assured, can be testified to by any intelligent observer. While the Exhibition is a matter of general interest to your readers, it may not be out of place to give a partial list of those exhibits representing matters to which the ENGINEERING AND MINING JOURNAL gives frequent and prominent attention.

The National Tube-Works has a very fine exhibit, a feature of which is the obelisk in the center of its space, upon which are fastened gauges, injectors, etc. The display of tubings of this concern is large and assorted. In cables, ropes, wires, etc., we may refer to the T. V. Allis Manufacturing Company, of Trenton, N. J.: George B. Carpenter & Co., Chicago; Harrison Wire Company, St. Louis; Roebling Sons, Trenton, N. J.; and Upson, Walton & Co. Cleveland, Ohio. In engines, there are the Ames Company; Southwark Foundry and Machine Company, Philadelphia; and the Westinghouse Machine Company, Pittsburg. The Bullock Manufacturing Company, of Chicago, is prominently represented by its engines, and supplies the Brush electric light. The Brown Hoisting and Conveying Company, of Cleveland; W. Chisholm & Sons, Cleveland, shovels, spades, etc.; Thomas H. Dallett & Co., Philadelphia, drills; Exhaust Ventilator Company, of Chicago, fans; Harrington & King, Chicago, Perforating Company; Huyett & Smith, Detroit, fans and blowers; Penfield Block Company, Lockport, N. Y., trucks, pulleys, etc.; W. H. Rickey, Cincinnati, hoisting machinery; David Bell, Buffalo, steam-hammers; Buffalo Forge Company, blowers and exhausts; Cleveland Steam-Gauge Company, forges and blowers.

Pumps and Water-Supply Machinery are exhibited by American Well Works, Aurora, Ill.; Blakeslee Manufacturing Company, Du Quoin, Ill.; Burkhardt's, G. J., Sons, cedar-tank, Philadelphia; Cammeyer & Sayer, hot-air engines, Chicago; Cameron, A. S., steam pumps, New York; Cloud Manufacturing Company, Detroit, Mich.; Delamater Iron-Works, New York; Davidson Steam Pump Company, New York; Deane Steam Pump Company, Holyoke, Mass.; Egelhoff Manufacturing Company, wind-mills, Milwaukee, Wis.; Gordon & Maxwell Company, Hamilton, O.; Hooker & Colville Steam Pump Company, St. Louis, Mo.; McCoy & Sanders, hydraulic tools, New York; Manning, Maxwell & Moore, New York; Nye & Palmer, Chicago; Poage, John N., water column, etc., Cincinnati, O.; Rodgers Iron Manufacturing Company, fire-pumps, Muskegon, Mich.; Reed, H. W., cypress tank, Waycross, Ga.; United States Wind-Engine and Pump Company, Batavia, Ill.; Van Duzen & Tift, siphons, Cincinnati, O.; Wells, F. C., steam pumping-engine, Chicago; Wilbraham Brothers, blower, Philadelphia; Worthington, H. R., hydraulic machinery, New York; Watertown Steam Engine Company, Watertown, New York.

Steam-Engine Supplies.—American Tube Works, injectors, etc., Boston; Allison, W. C., welded flues, Philadelphia; Ashton Valve Company, valves, Boston; Beaumont, R., stop-valve, Kankakee, Ill.; Butman Furnace Company, grates, flues, etc., Cleveland, Ohio; Baragwanath, William, steam-jacket heater, Chicago; Boston Belting Company, packing, hose, etc., Boston; Carpenter, G. B. & Co., asbestos, packing, etc., Chicago; Clow, James B. & Son, engine trimmings, etc., Chicago; Chalmers-Spence Company, covering for boilers, New York; Curtis Regulator Company, pressure regulator, Boston; Chicago Metallic Packing Company, Chicago; Detroit Lubricator Company, light feed-cups, Detroit; Elmira Steam-Engine Company, automatic lubricators, Elmira, N. Y.; Hotchkiss, J. F., boiler-cleaner, New York; Goodell, H. C., boiler covering, Chicago; Hawley, F. W., valve, Rochester, N. Y.; Ferris, J. H., socket wrench, Chicago; Kester, R. L., rod-packing, Philadelphia; Kunkle, E. B., lock-up valve, Fort Wayne, Ind.; Lonergan, J. E., cups, lubricators, Philadelphia; Marsh, James, gauges and test-pumps, Chicago; Merriam, T. & J., pipe covering, Milwaukee, Wis.; Manning, Maxwell & Moore, gauges, etc., New York; Magoon Heater Company Muskegon, Mich.; Nathan & Dreyfus, injectors, valves, etc., New York; National Tube-Works, Boston; Newcomb, W. W., link rest, Bradfordsville, Ky.; Purves, Thomas C., gauge, boiler-cleaner, Chicago; Parks, N. C., lubricating pad, New York; Reaser, W. J., slide-valves, Madison, Wis.; Richardson, F. W., valve motion model, Troy, N. Y.; Ryan, J. J. & Co., bearings, brasses, etc., Chicago; Riley, J. M., boiler covering, Troy, N. Y.; Sargent, Greenleaf & Brooks, pipes, ventilators, etc., Chicago; Schutte & Goehring, injectors, condensers, etc., Philadelphia; Shields & Brown, pipe and boiler covering, Chicago; Shelley, G., grate, Wilkes-Barre, Pa.; United States Metallic Packing Company, Philadelphia; Winona Machinery Company, cylinder packings, bearings, Winona, Minn.

Scales.—Borden, Selleck & Co., Chicago; Chicago Scale Company, Chicago; Fairbanks, Morse & Co., Chicago.

Many other exhibits are not yet in shape, but will be duly noticed in another letter.

UTILIZATION OF BY-PRODUCTS IN THE MANUFACTURE OF COKE.—II.

The Otto System.—The firm of Dr. Otto & Co., of Dahlhausen an der Ruhr, Germany, has paid considerable attention to the construction of coke furnaces, and has recently brought forward a number of modifications of a general design, the main points of which may be noted from the accompanying illustrations, Figs. 1 and 2.

The gases formed in coking are exhausted from the furnace through the pipes *E, E*, they being the only openings provided for their escape. Below the coking ovens proper are two flues, one below the other, and the vertical flues in the side-walls open alternately into the upper and lower horizontal flues, being designated in the illustration *O V* and *U V* respectively. Every one of the upper horizontal flues *O S* in the battery is provided with one or a number of injectors or burners *J*. The gases produced in coking are drawn off through *E* and taken to the apparatus where the tar and ammonia are condensed. After being deprived of these valuable products, the gases are forced back through the pipe *R*, and through the tuyeres *r* are conducted into the upper horizontal flue, where they are mixed with cold or preheated air, special provision being made to provide for lighting the gas. This horizontal flue is therefore the combustion-chamber. The hot products of the combustion flow through the openings *O O* upward through the flues in the side-walls, returning through the flues *U V* to the lowest horizontal flue *U S*, which connects with the main chimney flue.

Both the Carvés and Otto systems, it will be seen, are modifications of the Coppée oven, against which there is considerable opposition, both in this country and in England.

The Aitken System.—Mr. Henry Aitken, of Falkirk, uses a furnace which is very similar to the ordinary bee-hive oven, and was, we believe, the first to deal with the subject in England. Mr. Aitken provides three flues *G*, Fig. 4, in the bottom of the oven, about 4 inches square, and covered with tiles having perforations about ¼ inch in diameter on top and 1 inch in diameter on the under side. These three flues meet in one near the door, and into this flue the pipe *H* is inserted, which is connected with the condensers through which the gases are drawn by means of an exhauster. Mr. Aitken proposes to force the gases coming from the condensing plant into the ovens through the pipes *F*.

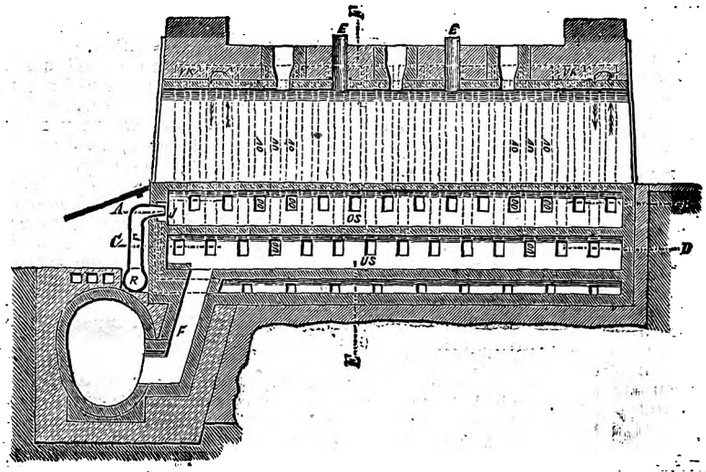

Fig. 1.

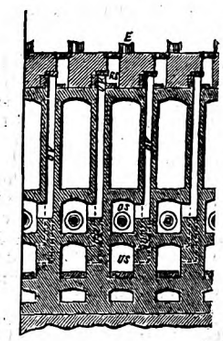

Fig. 2.

THE SPELTER PRODUCTION OF EUROPE.

In a sketch of the history of spelter, Herr C. von Ernst, of Vienna, has collected the following statistics of the production of spelter in Europe, which shows the growth of that industry. The unit is the metric ton:

	1858.	1881.
Silesia	38,000	67,547
Rhenish Provinces and Westphalia	15,400	32,520
Belgium, Vieille Montagne	27,000	49,600
Other Belgian works	9,500	44,211
England	7,500	15,186
France	500	10,445
Spain	1,500	7,032
Austria	1,050	4,230
Russia	1,500	4,300
Total	101,950	205,071

THE BAKER HORSE-POWER HOIST.—The one great obstacle to the first development of a mining claim has been the lack of cheap yet practical and effective machinery. The old-fashioned horse whim—always clumsy and uncertain—has done service from the first; but in these progressive days, this, like other crude appliances, is being laid aside and more convenient and reliable devices applied. Baker's mining horse-power hoist, says the *Rocky Mountain Review*, seems to meet all requirements, and is rapidly superseding all other devices of the kind. Large numbers are already in use in various parts of the country, with the most satisfactory results. The following are claimed as some of its advantages by the builders, the Pacific Iron-Works of San Francisco and Chicago: It is made entirely of iron, and is therefore very durable and not affected by climatic changes; no piece weighs more than 250 pounds, thus admitting of its being packed on mules to otherwise inaccessible localities; the hoisting-drum is under the complete control of the man at the shaft, and is capable of carrying 500 feet of five-eighths steel rope; a pulley may be placed upon the end of the drum in such a way that a pump can be run continuously without interfering with the hoist; at the ordinary speed of a horse, a thousand-pound bucket of ore can be raised at the rate of 120 feet per minute; the cost of erection is light, as two men in half a day are able to put it in place ready to work

A COMPARISON OF THE WORKING OF A BLAST-FURNACE WITH BLAST VARYING IN TEMPERATURE FROM 990° FAHR. TO 1414° FAHR.*

By Mr. W. Hawdon, Middlesborough.

The question of the advantage gained by working a blast-furnace with blast at a high temperature over that at a lower temperature has for some time past been much discussed; so much so, that the subject is considered by many quite threshed out; extreme high temperatures are considered the saviour of the pig-iron manufacturer in these days of keen competition, and that without such he will be left behind in the race. Only a few months ago, we heard of 5 cwt. of coke per ton of iron being saved by the application of brick regenerative stoves, producing, of course, high heats; while one of the oldest of the Cleveland smelters, in his inaugural address as President of the Cleveland Institution of Engineers, gave it as his opinion last year that, with a temperature of blast beyond 1000 Fahr., no further economy in fuel would result. So various have been the statements of the effect produced on particular furnaces, and so startling the saving of coke said to have been made in many instances when brick-heating stoves (which are the only means at the present day of obtaining a very high temperature of blast) were applied to these furnaces, that unless the varying circumstances of each particular case came under personal observation, it has been difficult for any one satisfactorily to account for the very much better order of things which prevailed under the new *régime*. The reduction of silicon into the pig-iron has always been a scare with many founders and forge managers when high heats are used in the reduction of pig-iron from the ore, and this demands refutation if the success of high heats is to be accomplished. The fact has been that in many cases before the application of the higher heats the furnaces have been relined, and stoves capable of securing a high temperature of blast have replaced those capable of producing a temperature of only from 500° to 700° Fahr. The effect of increased temperature on small furnaces, particularly under such improved conditions, has been a marked improvement and economy in the working of the furnace. It is my intention to give the experience which I have gained in the case of large furnaces, and with a blast already heated up to 1000° Fahr., by further raising the temperature to somewhat over 1400° Fahr. Part of the plant of the Newport Iron-Works of B. Samuelson & Co., Middlesborough, is composed of a separate and complete plant of three blast-furnaces, Nos. 6, 7, 8. Owing to circumstances, the center one (No. 7.) was blown out in October, 1861, and as it had been in blast since June, 1870, the stoves, which were of the ordinary lean-to U-pipe type, were necessarily much worn, and would require extensive repairs to put them in thorough working order. The writer visited several works where brick heating-stoves of the Cowper and Whitwell types were applied and high heats used, with the view of obtaining comparative information as to the saving effected thereby. Information freely given led to the expectation that the saving of from ½ to 1 cwt. of coke per ton of pig-iron would be effected by raising the temperature of the blast from 950° or 1000° to 1450° or 1500°, when applied to such furnaces as the one now specially under consideration, and that from 50 tons to 70 tons per week more pig-iron would be made. It was decided to pull down the old pipe stoves and put up brick regenerative stoves. These of the Cowper type were adopted, and I would just observe in passing, that it is not intended by any remarks here made to put forward the superiority of any one type of brick stoves over another, but merely to indicate the description of stove used. The furnace has not been blown in yet, and the new stoves were therefore available for work at an adjoining furnace. This opportunity has been made use of by the writer to note observations and obtain particulars in connection with the working of this furnace when using blast heated in the U-pipe stoves to a temperature of 990° Fahr., and in the brick stoves to 1414° Fahr. Blast at the higher temperature was turned on a few hours after the lower was cut off, so that we have an accurate comparison of the results obtained under the two conditions. The "Cowper" stoves, being built for No. 7 furnace, were placed at some distance from No. 8, so that the blast had to pass through a tube 4 feet 8¼ inches diameter and 67½ feet longer than is necessary if working the furnace for which the stoves were erected. This tube is lined with 14-inch fire-brick, and the loss of heat, taken by the thermometer on a calm day, was found to be 43° Fahr., in consequence of this extra tubing. The furnace in question (No. 8) was blown in February, 1872, and had therefore been in blast

*Read before the British Iron and Steel Institute.

Digitized by Google

for ten years—not a bad life for a furnace. But being in good condition, and in a thorough state of repair, the comparison does not suffer thereby. The furnace is 85 feet high from hearth to platform level, and has a bosh 27 feet diameter, which is built at an angle of 66½ degrees, or an inclination of 1 in 2·6. When the furnace was blown in, the well was 9 feet diameter. The tuyeres used are 5½ inches diameter at the nose, but the muzzles of the "belly pipes," which project into the tuyeres to within 8 inches of the nose, have been varied somewhat, according to the temperature of the blast, as hereafter stated. The cubical capacity of the furnace is 29,410 feet, reckoning to within 2 feet 6 inches of the under side of the bell, which is 13 feet diameter. The material used is Cleveland ironstone and limestone and coke from Durham. The coke is low in fixed carbon, having, according to analysis, only 88·8 per cent. This is probably accounted for by the fact that in process of manufacture the coal is only forty-two hours in coking, giving a yield of 67·75 per cent of coke. Were this coke manufactured under the ordinary long-hour system, whereby about 89½ or 90 per cent fixed carbon is obtained, the weight of coke used in smelting the iron would be proportionately lower. This should be borne in mind if comparison is made with the duty done by other cokes. The plan here adopted for comparison of the work done with different temperatures of blasts has been to tabulate the make of the furnace and yield of materials per ton of iron over periods of some weeks, giving the temperatures of the blast and the gas during each period. Calculating from an analysis of the gas, we obtain some check on the recorded yields given, and we are also enabled to give a comparison of the work done by the furnace under the varied conditions by comparing the sum of the heat units contributed from the two sources of supply—coke and blast—and which are the variable elements under consideration, together with the temperature of the escaping gases. These yields of the material used have been obtained by carefully weighing the barrows as they pass up to the furnace-lift. The yields for the seven weeks ended November 18th, 1882, were as follows, the average temperature of blast over this period being 990° Fahr., and the furnace working with the U-pipe stoves:

		Per Ton of Iron Made.				
Pig-iron made per week.	Quality.	Coke.	Limestone.	Calcined ironstone.	Purple ore.	Silicon in No. 3 pig-iron.
400 tons.	3·23	23·8	11·5	47·2	0·36	2·4 p. ct.

The small amount of purple ore, containing 64 per cent of iron, was used for "damping" the bells. The pressure of blast was 4½ pounds per square inch at the engine-house, and 4½ pounds at the tuyeres, of which there are five, the muzzles of four being 4¼ inches diameter, and one over the tapping-hole 3¾ inches diameter = 67·76 square inches area. The furnace was now connected with the brick stoves, which had been previously thoroughly dried. But as it was thought advisable at first not to press them, we worked with a moderate temperature only. The mean temperature over the next four weeks ended December 16th, 1882, was 1168° Fahr., the tuyere area and blast pressure being the same as before. The following were the yields for this period:

		Per Ton of Iron Made.				
Pig-iron made per week.	Quality.	Coke.	Limestone.	Calcined ironstone.	Purple ore.	Silicon in No. 3 pig-iron.
409 tons.	3·36	23·21	11·5	47·4	0·36	2·6 p. ct.

The coke, it will be observed, is reduced by 0·59 cwt. per ton of iron, while there is a slight increase in make; and as the silicon had somewhat increased, ¼ cwt. per ton of limestone was added to the charge. The diameter of the tuyere muzzles was now increased to 4¼ inches. The mean temperature over the two weeks ended January 27th, 1883, was 1295°. The following are the yields for this period:

		Per Ton of Iron Made.				
Pig-iron made per week.	Quality.	Coke.	Limestone.	Calcined ironstone.	Purple ore.	Silicon in No. 3 pig-iron.
449 tons.	3·35	23·02	12·12	47·4	0·36	2·5 p. ct.

Here it will be observed the make increased considerably, and there was a further small diminution in the coke per ton of iron, although the burden of limestone had been somewhat increased. The diameter of the tuyere muzzles was again increased to 5½ inches, and the mean temperature of the blast over seven weeks ended March 17th, 1883, was 1328° Fahr. The following are the yields:

		Per Ton of Iron Made.				
Pig-iron made per week.	Quality.	Coke.	Limestone.	Calcined ironstone.	Purple ore.	Silicon in No. 3 pig-iron.
461 tons.	3·14	22·8	12·16	47·25	0·35	2·6 p. ct.

A larger make, a somewhat better quality, and a farther saving of 21 cwts. of coke will be here noted. The iron at this time was dry and "rich" in appearance, an evidence of too much heat. The burden was therefore increased, with the following result, over the two weeks ended March 31st, 1883:

		Per Ton of Iron Made.				
Pig-iron made per week.	Quality.	Coke.	Limestone.	Calcined ironstone.	Purple ore.	Silicon in No. 3 pig-iron.
458 tons.	3·02	22·3	12·2	47·02	0·35	2·6 p. ct.

The temperature over this period was 1400° Fahr. The make was smaller than in the preceding period; but on account of short stoppages for repairs of the furnace, the working time of the furnace was shorter.

(TO BE CONTINUED.)

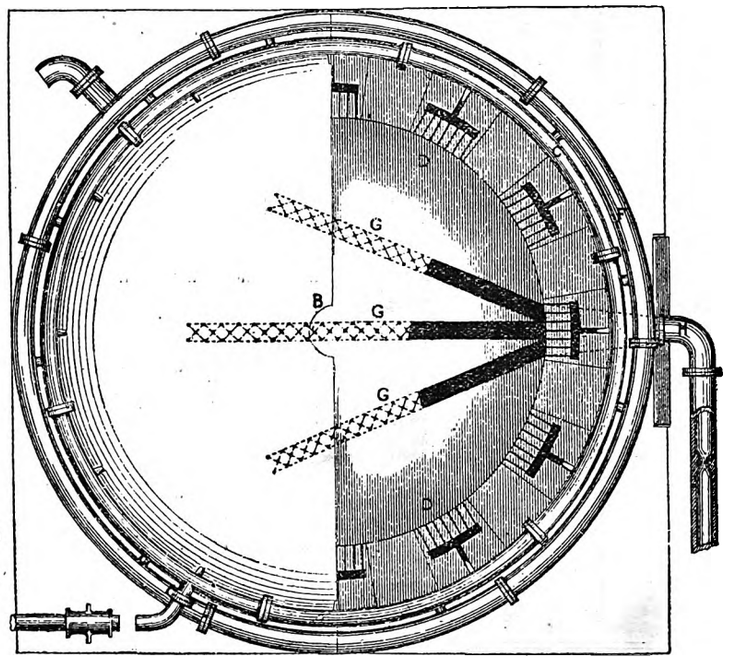

Fig. 4.

THE PRAT AND LAROCHE NICKEL EXTRACTION PROCESS.

MM. Jean P. Prat and Jules P. Laroche, of Bordeaux, have brought forward a process for the extraction of nickel from its ores which merits attention. They add the nickel ore, in a powdered form, to a bath of concentrated sulphuric acid, with a density of from 56 to 66 degrees Baumé, and agitate the mixture. A gradual heating of it takes place after two or three minutes, and it soon begins to thicken. A rapid and powerful reaction sets in, the temperature increases, and in half an hour the mixture assumes a greenish tinge and solidifies. The product, which contains the metals in soluble form, is leached in boiling water. To the solution thus obtained is added oxalic acid, and by prolonged boiling the sulphate of nickel is converted into oxalate, which is precipitated in the form of an insoluble paste. These well-known reactions are not claimed as part of their invention by Prat and Laroche, the features of their process being the treatment of the oxalate of nickel. They regenerate the oxalic acid by adding caustic soda to the precipitate and heating the mixture, thus producing oxide of nickel and oxalate of soda, from which the oxalic acid may be obtained by any of the well-known methods.

THE DETERMINATION OF MANGANESE IN SPIEGEL.*

By G. C. Stone, New Jersey Zinc and Iron Company, Newark, N. J.

In common with many members of the Institute, I was much interested in Mr. Kent's paper on Manganese Determinations in Steel,† read at the Virginia meeting. Having recently had an opportunity to collect a similar series of results for spiegel, I venture to offer them to the Institute, hoping that they may also prove of interest.

Sample No. 1 was taken at our works, where the spiegel was made. A portion of this sample was sent to one of our customers, whose chemist, A, obtained results different from mine. Portions of this sample were afterward sent to chemists C, D, and H. Sample No. 2 was prepared by A and myself with great care, and distributed to chemists C, D, E, F, G, H, I, and J. The results obtained are as follows:

SAMPLE No. 1.

Chemist.	No.	Manganese found.	Method used.
A	1	14·66	Acetate, bromine, and phosphate (average).
B	2	15·15	" and phosphate.
B	3	15·30	
B	4	15·11	Potassium chlorate and oxalic acid.
B	5	15·24	
C	6	14·92	Acetate and phosphate.
C	7	15·00	" " "
C	8	15·05	" bromine, and carbonate.
C	9	15·49	" " " "
D	10	15·05	
D	11	15·06	Volumetric method.
H	12	13·83	
H	13	13·98	

SAMPLE No. 2

Chemist.	No.	Manganese found.	Method used.
A	1	12·92	Acetate, bromine, and phosphate.
A	2	12·96	
B	3	13·38	" " " "
B	4	13·44	
B	5	13·53	" and phosphate.
B	6	13·68	
B	7	13·50	Potassium chlorate and phosphate.
B	8	13·58	
C	9	13·52	" " " oxalic acid.
C	10	13·68	
D	11	14·18	Acetate, bromine, and carbonate.
D	12	14·56	" " " "
E	13	13·46	" " " phosphate (average).
F	14	14·41	" " " ammonia.
G	15	14·47	" and bromine.
H	16	12·60	Potassium chlorate and oxalic acid.
H	17	12·72	" " " "
H	18	12·86	
I	19	12·20	" " "
I	20	12·44	
I	21	12·92	" " " "
I	22	13·05	
I	23	12·81	Same method, zinc added.
I	24	12·91	" " lime added.
I	25	10·36	" " alumina added.
J	26	12·95	Potassium chlorate and oxalic acid.

A few words as to the chemists and their methods.

A is a steel-works chemist of large experience. His method is as follows: Dissolve 0·5 gr. in hydrochloric and nitric acids, evaporate to dryness, take up with hydrochloric acid, filter; nearly neutralize by sodium carbonate, add a little acetic acid and sodium acetate, boil, filter, re-dissolve, and re-precipitate, evaporate the filtrates to small bulk, and precipitate by bromine, filter, wash, re-dissolve in hydrochloric acid (if any iron is present, nearly neutralize by ammonia, and precipitate with acetate of soda), and precipitate the manganese as phosphate, and wash thoroughly with hot water. A's results, whenever I have had an opportunity for comparison, have been lower than those of most other chemists. I think the reason is probably that he uses an insufficient amount of acetic acid when he precipitates the basic acetates, and by neutralizing the filtrate with ammonia he also loses manganese.

B is myself. Results 2 and 3, in sample I., and 5 and 6, in sample II., were obtained as follows: Dissolve 1 gram in nitric and sulphuric acids, evaporate till fumes of sulphuric acid are given off, dilute to 500 c.c., and take 200 c.c. (equal to 0·4 gr.) for each determination, add sodium carbonate until a decided precipitate forms, then 30 c.c. acetic acid (1·047 sp. gr.) and 7 or 8 grams of sodium acetate, dilute to 300 or 400 c.c., and boil gently about twenty minutes, filter boiling, and wash with very hot water, containing 3 or 4 grams of sodium acetate to the liter. Working in this way, I have never found any manganese in the precipitate, and very rarely any iron in the filtrate. Evaporate the filtrate and washings to about 200 c.c. (if any iron separates, filter it out), make acid with hydrochloric acid, and precipitate as phosphate as usual. A determination can be made in 7 or 8 hours. Results 3 and 4 in sample II. were made by precipitating basic acetates twice as above, then by bromine, and weighing as phosphate. Results 7 and 8, in No. II., were by Ford's method.‡ Results 4 and 5, in No. I., were by a modification of Williams's volumetric method.§

C is my assistant. His results, 6, 7, and 8, in No. I., were obtained by the acetate and phosphate method, as I use it. No. 9, in I., was by D's method. Nos. 9 and 10, in II., were by the modification of Williams's method, which I used.

D is a commercial chemist of considerable experience. Of results 10 and 11, in No. I., he writes: "Precipitated as basic acetate three times, separated the manganese by bromine and precipitated finally by sodium carbonate, washed by decantation, boiling after each addition of water until the washings gave no reaction with coralline. Results 11 and 12, in No. II., were obtained by precipitating as basic acetate twice, and separating the manganese as before. The analyses were made in a hurry, and the precipitates washed on the filter."

He was not entirely satisfied with the results, but considered 14·18 per cent the nearest to the truth.

E is a firm of commercial chemists, who have had an exceptionally large experience in spiegel analysis. They precipitate basic acetates, separate by bromine, and precipitate as phosphate. I do not know the exact details.

F is a commercial chemist. He used Troilius's bromine and ammonia method.* The results I think are high.

G is a commercial chemist. He used either Eggertz's or D's method, I am not sure which. His results are also apparently high.

H is an assistant in a prominent technical school. Sample II. was sent to him twice with different marks. His method, as I shall endeavor to show, is defective, and invariably gives low results; it is as follows: Solution in hydrochloric acid, boiling with large excess of nitric acid until all the hydrochloric acid is driven off, precipitation while boiling by potassium chlorate, solution of the manganese oxide in oxalic and sulphuric acids, and titration, with potassium permanganate, of the oxalic acid undecomposed. The oxalic acid is standardized by iron wire.

I is an assistant in the same technical school. He used the same method. 19 and 20 were his first determinations; 21 and 22 repeated "with great care." He also tried the method on manganese ores with results that compared more favorably with other methods. Thinking this might be due to the presence of some constituent of the ore, he repeated the determinations, adding zinc, lime, and alumina to the spiegel analysis; the results are given at 23, 24, and 25.

J is a chemist on the State Board of Health. He used Williams's method.

The acetate and phosphate method is, I think, the most reliable; all but one of the chemists on the list who use it agreeing well. It is hardly necessary to precipitate the manganese by bromine before precipitating as phosphate; for while it always gives slightly lower results, the difference is so small that it may safely be disregarded. I give some comparative results:

Sample No.	Manganese precipitated by bromine first.	Phosphate direct.	Difference.
39	17·02	17·10	0·08
76	13·38	13·53	0·15
76.	13·44	13·65	0·21
312	18·51	18·68	0·17
313	11·79	11·99	0·20
313	11·79	12·02	0·23

If there is ever any necessity for precipitating by bromine, it should be in our spiegel. As our ores contain considerable zinc, we use a very heavy lime charge, and the furnace-working is such as to favor the reduction of the alkaline earths.

The methods in which the manganese is precipitated as hydrate or basic carbonate usually give high results, owing to the obstinate manner in which the precipitate retains alkalies, although by washing by decantation, and boiling the precipitate each time with a large amount of water, it can be removed; but this takes too much time for a busy laboratory. D tells me that, although you may wash the precipitate on the filter until the washings give no reaction with coralline, yet if you then boil the precipitate up with water, it will give a strong alkaline reaction.†

Needing a rapid and tolerably accurate method for determining manganese in spiegel, I tried Williams's method as promising better than any that I knew of. On making comparison analyses by it and the acetate and phosphate method, I found that it gave me only about ninety per cent of the manganese, the difference being always proportional to the amount of manganese. The method is based on the supposition that manganese is precipitated by potassium chlorate from a nitric acid solution entirely as MnO_2. It occurred to me that this might not be correct; on trying it, I found it was not. To test it, I precipitated 0·5 gr. of a spiegel, in which I had previously determined the manganese by Ford's method, by potassium chlorate, and added the precipitate to a fresh solution of iron wire, made as is usual for standardizing permanganate, and, after dissolving, determined the excess of unoxidized iron by permanganate which had just been standardized by the same iron wire dissolved in the same manner. The results were as follows:

	No. 1.	No. 2.
Manganese found by Ford's method	0·0675	0·0679
Iron that would be oxidized if the precipitate were MnO_2	0·1374	0·1382
Iron actually oxidized	0·1117	0·1119

This result would give very nearly the formula 10MnO ,MnO. I then tried standardizing the oxalic acid solution by a spiegel which had been repeatedly analyzed by different chemists, and obtained excellent results.

The method of analysis finally adopted is as follows: Dissolve 0·5 gr. of spiegel in 40 c.c. nitric acid (1·42 sp. gr.) by boiling, add gradually an excess of potassium chlorate, cool, filter through asbestos (using a filter pump), and wash three or four times with water. The precipitate will still contain some iron, but it does not interfere. Add the precipitate and asbestos to an excess of standard oxalic acid (8 to 8·5 grams to one liter), add sulphuric acid, and heat till dissolved, titrate the excess of oxalic acid by permanganate (about 3 grams to the liter). The following are the results of *all* the test analyses I have made; most of the determinations are the averages of duplicate or triplicate analyses which agreed. A large number of the analyses were made by Mr.

My results, 4 and 5 in No. I., and C's results, 9 and 10 in No. II., were by this method.

I think the reason Mr. Williams found his results so satisfactory was, that he used steel containing about half of one per cent of manganese for all his analyses. With such a small amount present, of course the loss of one tenth of it (0·05 per cent) would make comparatively little difference.

I have some of the sample No. II. left, and shall be happy to send some of it to any member who would like to try it.

ANALYSES OF PRODUCER GAS.

In describing his methods for analyzing furnace gases, Mr. Magnus Troilius, of the Midvale Steel Company, gives the following figures as the results of analyses of producer gases. The producer used by Messrs. Hoopes & Townsend was designed by Mr. Ferdinand Philips, the mechanical engineer of that firm. Anthracite coal was used. The first analysis was made of gas from a producer into which blast was forced by means of a fan, while the others were worked by means of a steam injector. The figures are very instructive. The Midvale gas was made with bituminous coal:

	Hoopes & Townsend—Philips Producer.						Midvale—Siemens Producer.		
	No. 1a. Fan-blast. Hot-working producer.	No. 1b. Steam-blast. Cold-working producer.	No. 2a. Steam-blast. Just before cleaning producer. Bad coal.	No. 2b. Steam-blast. Bad coal.	No. 3a. Steam-blast. Normal running.	No. 3b. Taken 10 minutes after sample 3a, with air shut off as far as possible, and only steam let on.	Sample taken just after cooling down fires with water from below.	Sample taken just before cooling fires with water.	Sample taken just after cooling down fires with water from below.

MINE HAULAGE.

Mr. Thomas K. Adams, of Wheeler, Mercer County, Pa., Inspector of the Third Bituminous District of Pennsylvania, has collected a number of data from the superintendents of the mines in his district, bearing upon the question of the haulage of coal from the mines to the railroad tipples. He has requested information on the following points: The number of mules employed in their respective mines; number of tons hauled in ten hours; cost per ton for haulage for the different powers employed; the first cost of the different powers; maintenance of the same; distance the coal has to be hauled, and weight of coal in each mine-wagon, etc. Only eleven of the superintendents responded, nine of them being from Clearfield and Jefferson counties, one from Elk County, and the other from Clarion County. The data given below on mule haulage are taken for ten mines employing one hundred and fifty-seven mules, and having an average production of about seven hundred and nine tons per day. Three tests with locomotives are given, and with an endless and a tail-rope one each. Some of the mine managers reporting employ both mule and machinery for hauling purposes in the same mine, thus enabling them to judge more accurately of the efficiency and economy of the respective powers used:

Haulage by Mule-Power.

Average number of mules per mine	15·7
" " tons per mine daily	709
" " tons per mule per ten hours daily	45
" distance hauled for round trip per mule, feet	5347
" cost for haulage per ton	4·08c.
" first cost per mule	$171.50
" cost of feed and stable attendance per mule per year	$142.50
" weight of coal hauled in mine-cars, each, pounds	3649

Haulage by Locomotive, Endless Rope, and Tail Rope.

	Locomotive.	Endless rope.	Tail rope.
Average tonnage per day	807	900	1,000
" distances, round trip, feet	5,343	6,500	4,400
" cost of haulage, per ton	1c.	0·8c.	0·8c.
" cost of repairs for power per year	$150	$200	$150
" first cost of power used	$4,200	$4,000	$2,000
" weight of coal hauled in cars, each, pounds	4,160	3,000	4,480

It will be noticed by the above tabulated reports that one mule hauls forty-five tons of coal per day of ten hours, a distance of over one mile, at a cost per ton of $4\frac{1}{8}$ cents. This is certainly a very favorable showing for mule haulage, but is a better average than could be accomplished if the whole number of mines in the district were taken into consideration.

Out of the ten reports received on mule power, only two are given outside of Clearfield and Jefferson counties, thereby making the tabular reports more applicable to them than to any of the other counties. In these two counties, the coal-seam is much higher, roads drier, more favorable grades, and mine-wagons hold double the quantity of coal than the others. Mr. Adams has made an estimate on all the mines of the district, and does not think that one mule can haul more than thirty-three tons of coal in ten hours, and at an expense of about five and a half cents per ton, and over main and cross-entry roads laid with from fourteen to sixteen pounds T iron, and well kept.

Mr. Robertson, of the Dagus mines, Elk County, in his report, states that they have employed twenty-eight mules per day for the last six months. Mines running twenty-two days per month, with an average daily (nine hours) production of nine hundred and sixty tons, or thirty-four and two sevenths tons per mule, hauling the coal a distance of six thousand four hundred feet for the round trip. The load of coal in mine-cars is about twelve hundred weight. The road is laid with fourteen and sixteen pounds T iron, and well kept. Cost of drivers' (twenty-nine) wages alone is five and one quarter cents per ton. One locomotive, it will be seen by the averaged reports, does work nearly equal to eighteen mules. However, at the Sterling mine, No. 1, one locomotive does work equal to thirty-three mules, for nearly equal distances, with locomotive hauling against slight grade with loaded cars, while the mules have a grade in favor of loaded cars. The locomotive hauls from this mine daily eleven hundred tons of coal, a distance of six thousand three hundred and thirty-six feet for the round trip. The average first cost of locomotive is $4200, and average cost for repairs yearly $150. The average first cost of eighteen mules is $3274; average cost yearly for feed and stable attendance for eighteen mules alone, $2565. When the mines are not running, no expense is attached to the locomotive, except interest on investment; while the mules have to be fed whether they work or not; also, interest on them goes on. A larger percentage on mules, for depreciation and being killed, etc., must be allowed than on the locomotive.

Mr. Campbell, of the Sterling mines, Clearfield County, states: "We lose, by accident alone, fifteen per cent of our mule power, and nearly five per cent by the increasing of their age, yearly." This is rather above the average, however, as Mr. Campbell's mines have some heavy grades, and, by reason of this, his mules are more liable to be injured. There is some expense with locomotive not connected with mule hauling—such as making hauling roads larger, laying them with heavier rails, extra expense to keep them in repair, and keeping up separate means of ventilation. However, there are about three cents per ton saved by it, making allowance for these extras. These extras made necessary by the locomotive are avoided by using the endless-rope and tail-rope systems of haulage, and by adopting such means of haulage greater safety is given to the workingmen.

At the Franklin mine, Mr. Findley, superintendent, used the locomotive in the mine for about seven years, but has now withdrawn it, and hauls the coal by means of endless rope, retaining the locomotive outside and utilizing it as the power to drive the endless rope. It is giving better results than by the employment of locomotive alone. This power shows a production of nine hundred tons daily, hauling a distance of six thousand five hundred feet for the round trip, at a cost of eight tenths of one cent per ton; while the tail-rope system only shows a production of one thousand tons per day; distance of round trip, four thousand four hundred feet; cost per ton, eight tenths of one cent. But this is not near the efficiency of the tail-rope system. With the same machinery as employed in this test, over two thousand tons could be hauled for such a distance, had they adequate facilities in and about the mine to put more coal on side-track, and for tipping the coal outside. The endless or tail-rope systems ought at once to supersede locomotives and mules as a means of hauling coal from the mines. The longer the distance that machinery has to haul, in comparison with mules, the greater economy by its use. The best results obtained from mule-power are at the Rochester mine, Clearfield County; and from locomotive, at the Sterling mines, Clearfield County.

FURNACE, MILL, AND FACTORY.

The Porter Iron Roofing Company, of Cincinnati, O., manufacturer of sheet-iron roofing, has issued a new circular, giving a brief illustrated description of the chief features of this roofing, and a long series of testimonials from all parts of the country.

American diamond drills are doing good work on the Panama Canal.

The Chicago Steam-Engine Works are building several coal-hoisting machines for parties in Illinois, a quantity of stone-sawing machinery, one 150 horse-power engine for a brick-yard, and are also fitting up a macaroni factory with engine, boiler, presses, and other machinery.

Hinckley, Spiers & Hayes, proprietors of the Fulton Foundry, San Francisco, Cal., have erected a new molding-shop, 60 by 150 feet, which allows them to add their present molding-shop, which is 50 by 100, to their machine-shop, and gives them an area of 40,000 square feet. Lathes, drills, etc., will soon be placed in position. Some 300 hands are employed.

Mr. A. Aller, agent of the Pratt check-valve, of this city, has issued a reduced price-list.

The mechanical puddler in the works of the Phœnix Iron Company, Phœnixville, is reported to be working very satisfactorily.

The Steubenville Iron Company, with a capital of $150,000, has been incorporated. The company has purchased the plant of Sharpe, Daniels & Co., at Alikenna, O., including the valuable deposits of coal near the works.

The Watt Mining Car-Wheel Company, Barnesville, O., has just completed

Digitized by Google

another addition of 20 by 40 feet to its works, in which it has placed a trip-hammer and some other labor-saving machinery. It is working full-time on its specialty, self-oiling mine car-wheels and mine cars.

The Champlain Iron Company has purchased the machinery and patterns of the Ely Foundry Company, at Northfield, Vt., to be added to the stock at Champlain.

Two Corliss engines of 250 horse-power each are building at Providence, R. I., for a company of Chinese capitalists. They are to be used in a cotton mill.

A new addition, 237 by 40 feet and four stories high, is about to be made to the Pratt & Whitney Company's Works at Hartford, Conn.

An effort is making to dissolve the Iron City Forging Company, Pittsburg, an organization formed last February by John H. Bryce, H. A. Jones, John E. Morrison, and Samuel K. Duff. The latter gentleman was to have a two-thirds interest in the firm, in consideration of transferring to the company his two-thirds interest in a patent grate-bar. The matter was never consummated, and now the company wants to dissolve.

By satisfactory arrangement, the Cuyahoga Falls, Ohio, wire-mill property passes into the hands of Selah Reeve.

The Brier Hill Iron and Coal Company, Ohio, has leased the Ella furnace, at West Middlesex, Ohio, and is now engaged in operating it.

George J. Atkins and Frank L. Clark have sold their entire interest in the Forest City Iron-Works, at Cleveland, to Samuel J. Atkins, of Youngstown, and William Clark, of Pittsburg.

At the annual meeting of the E. T. Barnum Wire and Iron-Works, of Detroit, the following officers and directors were elected: E. T. Barnum, President and General Manager; Philo Parsons, Vice-President; F. H. Leavenworth, Secretary; Directors: E. T. Barnum, David Whitney, Jr., Philo Parsons, F. H. Leavenworth, Charles Parsons, of St. Louis.

There is building at the Marine Engine-Works, Chicago, one of a set of power-presses for working steel while too hot to work in the dies of a hammer or roll. The machine is intended to work up to 400 atmospheres, and will take the place of an hydraulic press. It is designed by Major E. B. Meatyard, of Geneva Lake, Wis.

The prospects are, that the blast-furnace on the lake shore at the north end of the city of Fond du Lac will be started up this season. The furnace was put in nine years ago by C. J. L. Meyer, and has never been operated. The buildings are of stone and very expensive; in fact, much more so than is at all necessary for the purpose. The facilities of this city for obtaining ore and for shipping the iron can not be questioned, and moreover, it lies on the direct route from the iron region to the great mills where the iron is worked up. A large number of men will necessarily be employed when the works start.

GENERAL MINING NEWS.

ARIZONA.

BRADSHAW.—At the annual meeting held in New York recently, the following directors were elected: Mr. J. S. Moore, Mr. Howard C. Dickinson, Mr. Clinton O. Field, Mr. Nathan J. Newwitter, and Mr. E. D. Barnes. The report presented shows that the debts due on the mill, as well as all other just claims, have been fully satisfied. "The company's property is entirely out of debt, and there is still a balance in the treasury." Several applications have been made to the management to buy the mill; but it would, under present circumstances, be very unwise to entertain such an offer, as the ore on hand and the prospect of getting more of it, will in itself warrant the retention of the mill and the property. Proposals for milling custom ore have also been made; but as the company is entirely out of debt and has no pressing wants, it is deemed advisable not to entertain any offers of that kind, unless they are clearly advantageous and remunerative to the company. Every effort will be made to develop the resources of the mine.

COCHISE COUNTY—TOMBSTONE DISTRICT.

The *Epitaph* says that the general work of the camp progresses steadily and energetically; those mines which have not reached water-level are doing their utmost to reach that point, as it is now a foregone conclusion that the developments beneath this level are likely to be productive of better ore than has been found above.

GILA COUNTY—GLOBE DISTRICT.

OLD DOMINION.—We understand that experiments are making at the smelting-works of this company to replace coke by the use of petroleum as a fuel in the water-jacket furnaces.

GRAHAM COUNTY.

A large body of hematite iron ore has been discovered two miles above Clifton, in the hills bordering on the Frisco River, and close to the wagon-road leading to Oro. Development-work has been begun on this property. The mine, which is a vast deposit of iron ore, has been called the Manganese. The cap-rock is lime, a strata of slag intervening between it and the ore. A cut 10 by 20 feet has been opened up, uncovering a well-defined ledge of iron ore, which shows 50 per cent of iron. It is proposed to go down twenty feet farther on the vein, and then run a tunnel into the hill on the ledge. Several tons of ore from this claim have been delivered to the Arizona smelters the past week, and it is stated that it works very satisfactorily for flux.

YAVAPAI COUNTY—PECK DISTRICT.

BLACK WARRIOR.—The Prescott and Tucson papers report the sale of the Tuscumbia mine and mill and the Tuscarora mine to the Black Warrior Mining Company, of New York, owners of the Black Warrior mine. The Tuscumbia and Tuscarora properties have good records as producers of high-grade ore. The mill is a dry-crusher, with a White-Howell roasting-furnace, and is of recent construction, embodying the latest improvements. During a recent run on a mixture of Warrior and Tuscumbia ores, notably high results were obtained, proving both the excellence of the mill and the advantage of mixing the ores. The Gus Springs water-right is included in the purchase. The union of these properties under one ownership is viewed in a very favorable light. It is expected that the mill will be started immediately, large reserves of rich ruby and brittle silver ores being available in the Black Warrior mine. The mill will hereafter be known as the Black Warrior, and the bullion be so stamped and consigned to the company in New York.

CALIFORNIA.

MONO COUNTY—BODIE DISTRICT.

BODIE CONSOLIDATED.—The official report for the week ended May 19th shows: Ore crushed, 181·44 tons; average assay value of pulp, $44.68 per ton; of tailings, $6.24. West cross-cut, 1000 level, is 230 feet long, and is in very hard rock. North drift from east cross-cut, same level, is 142 feet long. The vein is now somewhat wider than the drift, and the east wall will be followed. North drift, 800 level, is in 466 feet. Winze No. 5 is 22 feet deep; the vein is narrow. North drift from winze No. 6, 677 level, is 147 feet long. South drift from same winze, at the 640 level, is 161 feet long. Some very good ore is going to the mill from this drift.

STANDARD CONSOLIDATED.—The official report for the week ended May 19th shows: Ore extracted and shipped to mills, 1203 tons. North drift, No. 1, 1000 level, is in 120 feet, and shows the vein a foot wide. South drift No. 2 is 55 feet long; the vein is 2½ feet wide and looks well. North drift No. 2 is in 45 feet; vein one foot wide. Uprise from south drift, 700 level, is up 79 feet, where the vein is 2½ feet wide. West cross-cut from north drift is 241 feet long, and is in hard blasting rock. North drift No. 1, 500 level, is in 699 feet, where the vein is 10 feet wide. South drift No. 1 from west cross-cut No. 1 is 76 feet long, and shows 2½ feet of vein. South drift No. 2, 385 level, is 535 feet long; vein 5 feet wide. Uprise No. 1 from this drift is up 207 feet; vein 8 feet wide. North drift No. 3 is 143 feet long and the vein 7 feet wide. The stopes continue to look well.

PLUMAS COUNTY—GREENVILLE DISTRICT.

CRESCENT.—Eight stamps have been kept running; but after this, the company will run sixteen stamps until it is seen what developments may be made in the mine.

GREEN MOUNTAIN.—When the ledge was struck, the tunnel was continued on about forty feet beyond it, in order to make certain that it was the ore-body sought, and not a mere stringer. The result having been found satisfactory, a drift was then started along on the hanging-wall of the ledge; this is now in about 130 feet. Where the ledge was struck, it was found of the same width as in the stopes of the old workings, 400 feet above; as was expected, the ore did not prospect worth much, and for this reason the drift was continued alongside of, rather than in, the ledge; the latter being soft, would have required heavy timbering all the way, while in the hanging-wall the ground is solid and no timbering is needed. At short intervals apart, as the drift progresses, the ledge is cut into and the ore prospected; almost at any hour good pay may be found; there is a very confident assurance that a body of good ore will be cut into about 200 feet ahead of the present face of the drift.

CANADA.

PROVINCE OF NOVA SCOTIA.

OXFORD.—We are informed that this mine is doing well. The result of the run of the ten stamps last week was $3000. The Grey lode was struck last week, and from partial developments thus far is promising.

COLORADO.

CHAFFEE COUNTY.

MADONNA.—The reports from this company's property show favorable prospects. One of the peculiarities of this property is, that the ore is free smelting. The main tunnel has been run to a depth of 750 feet. Levels have been carried to an aggregate length of 800 feet, with shafts, stopes, and winzes, which in all can be safely put down at 500 feet. In the past month, a new tunnel has been started to cut the ore-body at a depth of 150 feet below former drifts. This work has been advanced to a length of 100 feet into the claim. The ore varies in value from 5 to 60 ounces in silver, and from 40 to 70 per cent lead. Assays have been had which show 1100 ounces in silver to the ton, yet these are not claimed as the representative average values. According to calculations made, there are at the very lowest possible figure 20,000 tons of ore in sight. At the present time, 50 tons per day can be taken out, and no doubt the output will be increased much beyond this figure when the railroad has been completed.

CLEAR CREEK COUNTY.

DIAMOND TUNNEL.—Ore filled with gray copper has been found in No. 5 lode west.

MOLINE.—The tunnel is producing large quantities of ore, and the mill is almost ready for work. The tramway is also rapidly nearing completion.

PAY ROCK.—The machinery at the mill is running satisfactorily.

WINDSOR.—The developments consist of a 70-foot tunnel on the vein which runs up and down the mountain. The breast shows from eight to ten inches of solid iron ore, assaying six and seven tenths ounces gold and seven ounces in silver. Depth at breast, thirty-five feet, and gaining faster all the time.

DOLORES COUNTY.

Mr. Linwood O. Towne, of Rico, sends us the following under date of May 25th:

GRAND VIEW.—Mr. Thompson Dean, president of the company, has been on from New York, and some important changes and additions will soon be made. The mines are producing regularly and well, and the smelter, under change of metallurgist from Mr. H. J. Hardess to Mr. Leon Eggers, has been running as usual.

LEILA DAVIS.—New shaft-house, ore-bins, etc., have just been completed, and work will be vigorously pushed by its owners, the Pasadena Mining Company, of St. Louis, under the efficient superintendence of its president, Mr. Watkins.

NEUMAN GROUP.—The present lease of this group is nearly up, and the intention of its owners for the future is not known. A large quantity of ore, milling nearly $500 per ton, has been regularly shipped by the leaser to the Grand View smelter from the Swansea, one of the group.

SANTA CLARA.—The reduction-works of this company are steadily running, producing gold and silver bullion.

SOUTH PARK.—This mine has within a few days changed hands; work has been progressing for some time and ore shipped to smelter.

STEVENS.—The first shipment of this mine for the season to the smelter has just been made, the ore milling over $170 per ton.

SILVERADO.—An important strike has been made on this company's property, fifteen miles below here on the Johnny Bull trail at West Dolores. The vein is two feet wide at a depth of only ten feet from the surface and assays 16 ounces of silver and 72 per cent of copper.

GILPIN COUNTY.

BOBTAIL.—Seventy-five stamps of this company's mill are kept running steadily, fifty of which are running on ore from the workings of the Bobtail tunnel, and twenty-five on ore from the Iron mine, in Russell District.

CALIFORNIA.—Sinking has been resumed on this mine, on Quartz Hill, and will be continued until a depth of 1500 feet has been attained. Plats have been cut at the 1400-foot station, and levels east and west are driving.

CYCLOPS.—The following development-work has been done since the organization of the company in November last: Main shaft sunk 135 feet, giving a present depth of 445 feet; winzes have been sunk covering 238 feet of ground; levels driven, 740 feet. Two plats have also been cut out, and 70 fathoms of ground back-stoped. The output of ore in the removal of the ground and in doing development-work has paid all expenses of the company to date. The company has in view sinking the main shaft to a depth of 800 feet.

SARATOGA.—The company will begin cleaning out the main shaft below the tunnel level. The tunnel level east cuts the shaft 120 feet deep.

GUNNISON COUNTY.

FOREST QUEEN.—The new working-shaft is now down sixty feet. It must be sunk fifty feet more before connection with the tunnel-level below will be made. It is said that sampling-works will be erected.

HINSDALE COUNTY.

HUDSON.—The shaft has now obtained a depth of 100 feet, and the vein has been cross-cut twice, once to a depth of 46 feet, and again on the lower level where the body of ore is now cross-cut. The breast is in solid mineral of the same character as that found in the first cross-cut, a copper ore, carrying lead, silver, and gold. This new level shows a richer and better ore. There are now about fifty car-loads of rich ore on the dump and in the ore-house ready for shipment.

LAKE COUNTY.

Late Leadville exchanges contain the following:

ADLAIDE.—It is stated that this property is to lease.

ARKANSAS VALLEY SMELTING COMPANY.—Four large furnaces are in blast.

Digitized by Google

The fifth furnace, which was relined some time ago, will be blown in again, when the smelter will be running at its full capacity. Owing to the amount of silica in the majority of ores, and the low percentage of lead, charges are made with a minimum percentage of lead, and the amount of ore reduced daily is estimated not to exceed two hundred tons. As a result, the bullion is of very fair grade —averaging about three hundred ounces of silver to the ton.

CARBONATE HILL.—The Yankee Doodle—the property of this company—continues showing considerable ore in sight. The product of this mine has now continued steadily at 300 or 400 tons a month for over a year, and more than $100,000 above all expenses have been realized from ore sales within that time. Since then, a great many improvements have also been made in the property, both on the surface and in the way of opening more through avenues for working the mine and extracting the ore. The main incline, which has been constructed within the past twelve months, has attained a total length of 1100 feet, and is still carried forward. The incline shows good work; is excellently timbered and laid with T rails. At the head of the incline is the hoisting plant, procured within the past few months, and which has the capacity of hoisting a loaded car of ore at the rate of 900 feet a minute.

COLONEL SELLERS.—This property, situated on the south side of Iron Hill, has been shipping for some weeks past. The mine is another one of the properties that have penetrated the ore-bodies below the water-level on the Iron Hill contact, and its yield consists of sulphides of iron, lead, silver, and zinc. Fortunately, the mineral is sufficiently high-grade to meet the additional charge of smelting, increased in consequence of the refractory character of the ore, and at the same time leave a handsome profit. Considerable ore has already been taken out, and, from all that can be learned, the mine is now self-sustaining, notwithstanding the many disadvantages under which it is laboring. A stope has been opened thirty feet in hight, all in ore, and levels have been driven east, west, and north, showing fine mineral, and promising to develop very extended reserves.

IRON SILVER.—The managers, who have always shown considerable enterprise in prospecting and experimental exploration-work, conceived the idea, some time ago, of prospecting the fault crevice west of the outcrop of their mineral belt. About two months ago, arrangements were completed for beginning this work, and a location selected south of the south incline building of the Iron Silver mine, near the line of the Silver Cord property. An incline was started, following the fault crevice at a pitch of about seventy-five degrees to the west, which, up to the present time, has attained a depth of seventy feet. The crevice averages about three feet in width, occasionally widening out and again contracting, and disclosing segregated and broken masses of ore. Just now, the crevice is contracted until but little mineral is left; but on an average sufficient ore has so far been secured to defray all the expenses incurred in carrying on the work. The incline will be continued to a still greater depth.

LA PLATA.—At a meeting of the La Plata Mining and Smelting Company, in London, Mr. William Abbott stated that the debt of the company, incurred in continuing dividends, amounted to £38,000 on January 1st, and had been reduced since to £25,000. The following resolution was passed: That this meeting, having heard the statements laid before them by the committee of shareholders, approves of the formation of an English limited company, with a capital of £400,000, in 400,000 shares of £1 each, and strongly urge the shareholders in the existing American company to forthwith exchange their shares in that company for two £1 shares in the English company, and that the committee be authorized to take the necessary steps to form the said company accordingly, and issue the shares thereof in exchange for shares of the American company.

LEADVILLE CONSOLIDATED.—Mr. O. H. Harker has retired from the management, and Mr. John T. Elkins has been appointed to the position.

MANVILLE SMELTING COMPANY.—This company, recently organized in Leadville, has leased the Elgin Smelting-Works for one year.

MIKE & STARR.—Quite recently, a body of ore was opened on the 426-foot level, and since then development has been continued, until at present the mine shows quite a well-defined chute of pay-ore about fifty feet in width, having a nearly north and south trend. The mineral is a sulphide of lead, copper, and silver, ranging in value from five to forty dollars per ton above smelting charges. The ore is bedded on a metamorphosed limestone, with a cap of porphyry, differing but slightly from the inclosing rock of the ore-chutes on Iron and Carbonate hills generally. The ore-chute has been opened for nearly one hundred feet along its course, showing an average width of fifty feet and a thickness ranging from six to fourteen feet.

TABOR MILL.—This stamp-mill has been destroyed by fire.

SUMMIT COUNTY.

ROBINSON.—The engine on the trial concentrator has been started up. Mechanically it works to perfection, and so far as can be judged at the present time, the dry method is a success. If it so proves after further experiments, concentrators having a capacity of 150 tons per day will be erected immediately. The ore-body below the twelfth level continues to increase in grade; but its thickness at present is unknown, as the bottom of the incline is in ore and no winze has been sunk to ascertain its extent. A large force of men is employed in the mine and development-work is progressing rapidly.

DAKOTA.

A dispatch from Deadwood says that the late floods were very disastrous to mining interests. All the mills were compelled to shut down, owing to water in the mines, the impassable condition of the ore-roads, and wash-outs on the wood railroads. The only mills now in operation are the Homestake 80-stamp, the Highland, Deadwood, and De Smet. It is expected that the repairs of the railroads will be completed shortly, and that the principal idle mills will start up within the next few days. The loss to the mining interest is estimated at $200,000; the loss to the country at more than half a million dollars.

FATHER DE SMET.—The report of the superintendent, from May 15th to May 22d, shows ore extracted from first, second, and third levels, 1000 tons. Ore milled, 1100 tons. From the 18th to the 21st of May, partial suspension of mill working, in consequence of high water. Golden Gate north header advanced 6 feet. Header in 111 feet.

GEORGIA.

CHESTATEE.—The cut is now seventy feet deep, and progress into the hill slow.

COLUMBIA.—The mill will soon be running on ore from the late purchase.

GARNET.—Development-work is rapidly pushed. When it is fully equipped, it is expected that mining and milling will be done at a cost of less than twenty cents per ton.

SINGLETON.—The new water-power mill on the Lockhart property is running regularly on ore from the stopes, and all indications seem favorable.

IDAHO.

MOONLIGHT.—Work has begun at this mine.

SMOKY BULLION.—A report states that this mine has been sold to some Pennsylvania gentlemen for $25,000. A company incorporated under the laws of the State of New York has been organized, with a capital of $200,000. Operations will be begun at once.

MAINE.

The Bangor *Mining Journal* says that many of the companies are preparing for active work during the coming season. Extensive and satisfactory operations are carried on at the Douglass, Stewart, Blue Hill, Cape Rosier, Manhattan, Sullivan, Milton, Mascot, Milan, and the Winslow tin mines, and also at several other localities in the State; while arrangements are perfecting for an early resumption of work at the Cherryfield, Gouldsboro', Hercules, and several of the Blue Hill mines. The mines now worked are showing as favorable indications.

MEXICO.

ALMADA AND TERITO.—This mine yielded a profit of £2380 in 1882. Mr. Clemes, the manager, estimates the profit for the first three months of the present year at £3150.

Marble similar to what is generally known as the Puebla onyx has been discovered in the State of Chihuahua. A company is already organizing to work the quarries.

CANDELARIA.—The operators are systematically opening this mine. All through the mine are large bodies of rich ores running from $500 to $1500 of silver per ton, and on the completion to the vein of the lower tunnel, now running, a block of vein-matter will be laid open. With this tunnel completed, it is estimated that the ores can be mined and put in mill for less than $5 per ton, or at a total cost for treating not exceeding $17 a ton. The owner of the mine has spent during the last six months $42,000 in preparatory work. The mine is sufficiently open to permit a daily extraction of 100 tons of ore.

ROSARIO.—The engine working to unwater the mine has drained to a depth of about 225 feet, leaving about 45 feet more of water to take out. Some recent assays of ores ran $120 to the ton. This mine had been for many years unworked until the advent of the present company, which, encouraged by the reports of its former richness, proceeded to unwater the property. As the water has been lowered, rich vein-matter has been revealed.

SANTA EULALIA.—Two hundred men are employed erecting hoisting-works, stamp-mills, etc.

ZIMAPAN COPPER MINING COMPANY.—The one furnace now operating gives entire satisfaction, and three more will at once be erected.

MONTANA.

MADISON COUNTY.

The district known as Tidal Wave, situated in the range of mountains bordering the Jefferson and Ruby rivers, says the Virginia City *Madisonian*, is one of the most promising of the quartz-mining sections of this county, and the developments made and in progress, together with the favorable prospects which it has of being supplied at an early day with works for the reduction its ores, give it prominence as the nucleus of an important mining camp.

DRUM LUMMON.—*Money*, an English newspaper, sharply attacks those who floated off this mine, which was incorporated as the Montana Company. The owner, Mr. Thomas Cruse, was to receive £125,000 in all, part of which has been already paid, while the vendors, the Joint Stock Association, in which it appears Baron Albert Grant is interested, were to get £175,000.

SUMMIT VALLEY DISTRICT—SILVER BOW COUNTY.

ANACONDA.—The site for the proposed smelter has now been definitely decided upon. The works will be built on the north side of Warm Springs Creek, facing south. On the opposite side of the creek, the new town, to be named Copperopolis, is to be located by the company. The work of constructing the smelter will begin at once.

BELL.—One of the largest runs ever made at this smelter has been recorded. Over 50 tons of material were dumped into the furnace, of which 36 tons were ore. The matte output of the smelter averages about ten tons per day, assaying 50 per cent copper and from 50 to 75 ounces in silver. The ore supply on hand is yet abundant, and will in all likelihood last until the extraction of ore from the mine is begun from the new workings. The shaft is now 300 feet deep, and the 300-foot station will be put in and another cross-cut started to the ledge. Sinking will then be continued to the 400-foot station, and the main ledge will again be cross-cut and fully explored.

MARIA.—This prospect is about a mile north of the Alice. The developments consist of several shafts sunk to water-level and drifts running east and west on the vein at different places. The main shaft, in which work is now prosecuted, is 50 feet deep, and the level extends 30 feet each way from the bottom. In each drift, the ledge shows a uniform width of seven or eight feet, of which rather more than one half is pay-ore, two feet of it assaying from 70 to 100 ounces in silver. Only a small force is employed at present, but regular ore-shipments are made to the mills.

POSER.—In a cross-cut run from the 100-foot shaft recently sunk, an important strike has been made. It is stated that the assays so far made average $3.

NEVADA.

ALBION.—On May 19th, the personal property of this company was sold at the mine for $23,277. The Eureka *Sentinel* says that the actual value of the property sold is estimated at $70,000. The coal sold for barely more than half what it is worth. The mine will be sold under execution June 1st, and will doubtless pass into the hands of the Nevada Bank, the heaviest creditor.

EUREKA CONSOLIDATED.—Another furnace has been started at the reduction-works. The bins at the works are filled at present with Eureka Consolidated and tribute ores. In starting up another furnace, the hope is to get the mass of this ore out of the way, in anticipation of increased shipments from the Eureka tunnel in a few days, upon the completion of the new shaft, through which it is calculated ore will begin to be hoisted shortly. It is understood, also, that arrangements will be completed within a very short time by which ore will be allowed to be shipped for reduction from the Albion. The tributers in this mine are reported to be doing very well in their pitches, from which, and from other parts of the mine generally, it is believed ore enough can be shipped to help out materially in keeping one furnace at work. It is probable that enough custom ores will be shipped to the works to keep the additional furnace running for some time.

UTAH.

SUMMIT COUNTY.

APEX.—Work is going on at the top of the ore-chute, and may open up a large ore-body in the belt of the ore zone.

CRESCENT.—The ore at the upper workings is low-grade, and as depth on the vein is attained, it grows richer, bringing the average well up.

WASHINGTON COUNTY—SILVER REEF.

STORMONT.—The superintendent reports an exceedingly rich strike at the foot of winze No. 23. Fifty-four inches of vein assayed as follows: 15 inches, $193.27 per ton; 15 inches, $5.33 per ton; 12 inches, $52.16 per ton; 12 inches, $26.71 per ton. He also reports that the uprise in fifth north level has cut a favorable-looking streak of petrifactions, showing that the vein is overhead, as expected, and that he shall continue the uprise far enough to prospect both veins. A telegram received at the New York office of the company on Saturday says: Winze still shows good ore. Prospects for next month good.

VIRGINIA.

Work at the pyrites mines at Tolersville has begun, and everything will be ready to ship pyrites by the 20th inst.

active and irregular; it sold from 22@38@26c., with a business of 149,605 shares.

The Leadville stocks were very quiet, and prices were steady. Amie Consolidated was quiet and irregular at 18@21@19c. Chrysolite had a small business, and was steady; it sold at $1.10@$1.15. Hibernia sold at 4c. Iron Silver was moderately dealt in at steady prices; it sold from $3.05@$3.10. Little Chief was very quiet at 50c. Little Pittsburg had a small business at steady prices, selling from 78@80c.

The Bodie stocks were almost neglected. Bodie Consolidated sold at $1.15, with a transaction of 100 shares. Standard was quiet and a little weak, selling from $6.75@$6.13. North Standard had a small business at steady prices, selling from 15@20c.

The Tuscarora stocks were very quiet. Argenta sold at 90c. Navajo had a fair business and was weak; it sold from $1.80@$1.35@$1.45, the transactions amounting to 4200 shares. Elko Consolidated was quiet and steady at 20@19c.

In the miscellaneous list, Alice was quiet and strong at $3.25. Bassick sold at $7.50, with one small transaction. Caribou Consolidated was quiet and steady at 13@14c. Eureka Consolidated sold to the extent of 600 shares at $3.25. The Green Mountain stocks were very quiet at steady prices. Gold Stripe sold at 8c. Rising Sun sold at 4c., and Cherokee at 3c. Homestake was quiet and strong, selling from $15@$16. Horn-Silver records a small business, at prices a little weak; it sold from $6.75@$6.50

Digitized by Google

Hukill sold at 8c. Northern Belle, under a small business, was steady at $6.50. Ontario was moderately dealt in, and was strong; it sold from $25@$26, the transactions amounting to 490 shares. Robinson Consolidated has been quiet and irregular, selling from 89@79c. @82c. Sierra Grande was very quiet, selling to the extent of but 200 shares at $1.15. Silver King was quiet at $10⅝.

Alta-Montana was moderately dealt in at 4c. American Flag records a small business, and sold at 5c. Central Arizona sold at 30c., with one transaction. Decatur had a fair business at irregular prices; it sold from 6@8@7c. Dunderberg sold at 25c. Harlem was very quiet and sold at $1.40. Hortense, with a small business, sold at 10c. Lacrosse was quiet and steady at 13c. Oriental & Miller had a very active business at very irregular prices; it sold from 16@24@20c. Rappahannock sold at 7@9c., with a fair business. Silver Cliff was quiet and steady at 17@19c. Sonora Consolidated had an active business and has been very weak; it sold from 70@42c., the business aggregating 45,100 shares. South Pacific was active and steady, selling at 8@7c. The State Line stocks were active and steady; Nos. 1 & 4 sold from 3@5c., and Nos. 2 & 3 from 4@7c.

PIPE LINE CERTIFICATES.

The petroleum market has been very strong this week, and very active. This strength is not due to good news from the oil regions, but to a strong bull syndicate that has been manipulating the market. In fact, instead of a dearth of oil, the United Pipe Lines report up to May 27th an increase in visible supply of 110,908 barrels for the month. The monthly oil report, however, shows that during the month 226 wells were completed, with a daily production of 3908 barrels. This, as compared with April, shows an increase of thirty-one in the number of wells, but a decrease of 1,080 barrels in the production. There are now 381 rigs up and wells drilling, against 403 at the corresponding time last month.

News from the oil regions has not been abundant. On Saturday last, it was reported that the Anchor Company's well No. 6 struck the third sand and was a good producer of about 300 barrels. Since Tuesday, the news received has been of a more bearish character. Grandin No. 8 is estimated to be equal to 100 barrels a day. The Stewart well No. 2, east of the Cooper tract, opened with 240 barrels flowing in the first seventeen hours, the position of the well indicating an extension of the new producing territory. Welsh No. 2 also came in and made 580 barrels the first twenty-four hours, but has declined since to about 400 barrels per day. The Balltown production, 16 wells, is 1699 barrels. Other bearish facts may be given, such as an important decline in charters and an increase in stock on hand. These facts would intimate that the strong prices for oil now ruling are purely fictitious, and lower prices may soon be looked for.

A committee appointed by the New York Mining Stock and National Petroleum Exchange to nominate officers to serve the ensuing year has reported the following ticket:

President, C. O. Morris; Treasurer, John Stanton; Chairman, A. W. Peters; Secretary, J. B. Sweeney; Assistant-Secretary, R. H. Gallagher. Governing Committee, to serve one year—C. G. Falls and Julius Johnes; to serve three years—G. F. Mann, G. B. Satterlee, A. Peckham, S. V. White, J. S. Stanton, L. V. De Forest, F. F. Beals, C. L. Parker, and J. Mulhaney. Trustees Gratuity Fund—R. H. Bonnell, S. V. White, and H. H. Truman. Mr. A. Peckham having declined to serve, Mr. R. M. Shaw was nominated to fill the vacancy.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

		Opening.	Highest.	Lowest.	Closing.	Sales.

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, May 31.

There is no activity in the market for copper stocks, and the sales of the past week have been smaller than ever. There is, however, a firmer tone, and prices are a shade higher, but there is no life to the market; no disposition to buy and but little to sell; in fact, orders either way are scarce, the public generally not being in a speculative mood. Ingot copper is steady, and a slight advance in this respect would tend materially to improve the market for the shares of the producing mines, and impart a little impulse to speculation. Calumet & Hecla advanced from $232½@$234 on sales of seven shares each on three alternate days of the week. Quincy improved from $43½@$45, but subsequently sold at $44½, and a small lot at $44, seller 60. Osceola also advanced from $21@$21½, on small sales. The rest of the list was entirely neglected, not a sale recorded for the week in any of the speculative or non-dividend-paying mines.

In silver stocks, the principal dealings have been in Sullivan, to which we referred last week. The sales this week have aggregated about 3000 shares at an advance from $1⅛@$2¼, closing sale being at $2⅛. We are told that much higher prices may be looked for in this stock. Catalpa, steady but dull at 65@67½c. The mine is looking well, and the prospect for continued dividends encouraging. Crescent sold at 30c. San Pedro declined from 40@35c.

At the Mining Exchange, there is no special feature of interest, and prices of the stocks dealt in are not materially changed.

3 P.M.—The market this afternoon shows no improvement, but prices are steady. Bonanza Development sold at $2½. San Pedro, 40c. Franklin, $10 bid, $10¼ asked. Quincy, $43 bid, none offered. Pewabic, $3@$4. Silver Islet, $4 bid. Sullivan, offered at $2¼, no bid. Catalpa, 55c. bid, ex dividend 10c. Crescent, 25@30c. Harshaw, $½ bid.

BULLION MARKET.

NEW YORK, Friday Evening, June 1.

The market is somewhat firmer abroad without quotable change, and "sterling" is higher here—making, for the present at least, a feeling of more confidence.

Date.	London Pence.	N. Y. Cents.	Date.	London Pence.	N. Y. Cents.
May 26	50⅛	109⅝	May 30	50⅛	Holiday.
28	50⅛	109⅝	31.	50⅛	109¾
29	50⅛	109⅝	June 1.	50⅛	109¾

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table

is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14½ per cent, to arrive at actual value.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended June 1st, as compiled from various sources, amounted to $117,000, as against $133,000 reported for the previous week. The receipts from January 1st, 1883, to date are $5,235,713.53.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended May 26th	$145,774
Corresponding week last year	2,850,551
Since January 1st, 1883	5,691,911
Corresponding period last year	28,654,148

Imports.

Week ended May 26th	$36,525
Corresponding week last year	84,695
Since January 1st, 1883	6,688,933
Corresponding period last year	1,714,227

Foreign Bank Statements.—The governors of the Bank of England, at their weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 4 per cent. During the week, the bank gained £367,000 bullion, but the proportion of reserve to its liabilities was raised only ⅛ per cent, to 35¼, against 40 11-16 per cent at this date last year. May 31st, the bank made a further gain of £104,000 bullion on balance. The weekly statement of the Bank of France shows a loss of 3,425,000 francs in gold, and a gain of 107,500 francs in silver.

METALS.

NEW YORK, Friday Evening, June 1.

Copper.—Current business is small, but there is an undertone of interest that gives promise of early development. Bids have been made for Lake copper for export, the figure named being 15⅝c., but as yet no sale has been consummated. At the same time, we hear that negotiations are pending for the sale, for export, of a large stock of copper from an Arizona mine. The views expressed in our editorial columns thus find confirmation, although at the moment of writing we were not aware that matters had assumed their present shape.

The only transaction worthy of note is the sale of a 100,000-pound lot of Lake at 15⅞c., which, it is presumed, comes from a mine. This is supposed to indicate that some of the smaller Lake companies are acting independently, and are beginning to force sales, so that a falling off of prices is not among the impossibilities, unless the position of Lake is strengthened by export. We quote Lake copper 15⅞@16c., and other brands, 14½@15⅝c.

Ores are quoted 12@12s. 6d. per unit, in England.

Tin.—This metal has been dull and has weakened. The Banca sale in Holland went off at 58 guilders, which is about the parity of London, which quotes by cable to-day £94 15s. We quote for round lots of Straits tin 21½c., and Australian 21¾@21⅞c. asked.

Lead.—Very little has been done, sales aggregating only 400 tons of various brands Refined and Common at 4·40@4·45c., which we quote. The best bids for 600 tons of Germania spot and to arrive were 4·32½c., which was delivered, the parties at headquarters in San Francisco asking 4·50c.

Messrs. John Wahl & Co., of St. Louis, wire us as follows to-day:

Our market is firm. It has shown remarkable activity since our last advices. Sales for the week sum up over 500 tons of Chemical lead at 4·12½c. We quote Refined lead at 4·15@4·18c.

From Chicago, Messrs. Everett & Post send the following dispatch:

Our market is quiet but firm at 4·15@4·17c. Sales aggregate 300 tons during the week of Common and Refined.

Spelter.—This metal is dull and weaker, ordinary Domestic selling in small quantities at 4·60@4·65c. Silesian has sold at prices equivalent to 5c., but we quote the same at 5@5⅛c.

Antimony.—Antimony is lower; we quote 9⅝@9¾c. for Hallett's and 10⅝@10¾c. for Cookson's.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, June 1.

American Pig.—The market is dull and weaker, and we hear that Allentown foundry is offering iron at $20. We have no sales of any importance to record, and quote ordinary to choice foundry brands, No. 1, $21@$22; and No 2, $19@$20, nominally, with the market strongly in buyers' favor. Forge iron in the East will probably suffer under the continuance of work in the Western mills. We quote $17.50@$19. Bessemer pig

Digitized by Google

is quiet at $21@$22, at tidewater, while Spiegeleisen, 20 per cent, is quoted $31@$32.

Scotch Pig.—There is absolutely no change in Scotch iron. Transactions are on a limited scale, in very small lots exclusively, so that our quotations must be considered nominal. We quote: Coltness, ex ship, $24@$24.50; Glengarnock, $22@$22.50; Eglinton, $21; Langloan, $23.50@$24; and Summerlee, $24. Warrants are cabled 46s. 10d.

Rails.—The mills are well supplied with orders, though it is generally understood that the business was secured by making concessions. Now, however, $38 at mill is the ruling quotation.

Old Rails.—There is nothing of interest to report. Business is dull and quotations remain nominally $22.50@$23 for Ts.

Scrap.—Dealers are generally so well supplied that they are entirely indifferent. Most of them are unable to market their stock at any thing like remunerative figures, and Scrap is therefore neglected at $23.50@$24 for No. 1.

Philadelphia. June 1.

Enough furnaces have gone out of blast during the past ten days, and will go out of blast during the next ten days, to impart the needed improvement to the crude iron industry. Pig-iron makers hold on to the last hour, and a great many were suddenly seized with the conviction that a suspension was immediately necessary. There will be a sufficient demand to absorb the production of those that still remain in blast. The stocks are large, but it is likely that large consumers will take advantage of the extremely low rates at which these stocks can be secured, and purchase for several months' requirements. Ordinary quotations, delivered, are: $18@$19 for Forge, $19@$20 for No. 2, and $21@$22 for No. 1 Foundry. During the past week, some extraordinary concessions have been made and offers presented. Forge iron has been bought at $17 at furnace, and, it is said, at a little less, though this is not authenticated. No. 2 Foundry is moving downward, and some buyers expect to purchase under $19. Foundry iron is moving between $20 and $21 for some brands. There is a general unrest among holders, and each one is in a hurry to get out. It is probable, in the opinion of some far-seeing iron men, that, as soon as the present panicky feeling is past, the price of pig-iron will settle down to a little above cost limits. The prospect of a Western strike has weakened crude iron and improved finished iron. There have been attempts to sell Bessemer for summer shipment, but makers are not disposed to make necessary concessions.

Merchant Iron is in better condition than at any time since the opening of the year. Orders for Refined are taken at 2·20c.; small orders, 2·25c. Stores are selling at card rates, chiefly. Some buyers have covered 60 days' requirements. Nearly all buyers are purchasing more than they have been. Inquiries are also more frequent, and there is generally a better feeling pervading trade circles. Country mills are getting better prices, especially for common iron, the business of which they seem to be able to monopolize. Orders for a few hundred tons for early and summer delivery have been placed at prices in and around 2c. Concessions are not easy to get. There is more confidence among manufacturers. Skelp iron has been moving in large lots at about 2·20c. The upward tendency in nails is developing, and some jobbing lots were sold at $3.20. Makers are less disposed to sell for future delivery, and in large lots, as they think it better to husband their stocks and take advantage of improving demand. Inquiries are crowding along and the outlook is more encouraging than it has been.

A few good orders for *Wrought Pipes* were booked, and boiler tubes are in fair request Quotations are unchanged, although, for the orders reported, concessions were made. Galvanized iron has been quiet for several weeks, but two or three large orders were placed. Card rates are unchanged. Buyers are purchasing more freely, and for later deliveries. Stocks are very low in consumers' hands, and, as prices will not weaken, they are looking out for supplies.

Boiler Plate has been wanted in larger lots than usual. Common Plate iron is selling at $2·40c.; Shell nominally at 3¼c.; Flange, 4¼c.; Fire-box, 5¼c. Manufacturers are not adhering to these figures except in retail lots. Nothing is done in a large way, although, after the first of July, it is probable that some business that has been held back for the earthquake in prices, will be placed.

Structural Iron.—Manufacturers of shape iron have been doing a retail business for several weeks, but a few inquiries for large lots have finally been received, which, if placed, will make business better for the summer. There are sufficient requirements, but buyers have been hesitating for a long time. Angles are 2·40c.; Beams and Channels, 3½c.; Tees, 3¼c. Some makes of iron have been selling from two to three tenths below these figures, but it is doubtful whether they will stand Pennsylvania Railroad tests. A good deal of bridge building has been brought to light, and negotiations are now in hand for it.

Bessemer mills have secured orders for between 20,000 and 30,000 tons of steel rails at $38@$39; and if pending negotiations are closed, June business will compare very favorably with former months. Summer orders are coming along at about $39@$39.50, and occasional sales of light sections are made $2@$3 higher. Old rails and scrap are unusually dull, and negotiations have been hanging fire a long time without result.

Pittsburg. May 31.

The last week of work for probably three or four months finds the iron trade artificially active, and buyers anxiously covering pressing requirements for from thirty to sixty days. Manufacturers have all along refused to depart one iota from the programme marked out at their meeting, and are to-day as confident and as resolute as at the start. They have supplies of iron on hand which will allow them to meet actual requirements of th ir customers, and there are indications that in some portions of the West, some mills will be started in a few weeks with non union labor.

The efforts of holders of pig-iron to sell meet with no success. Forge is an absolute drug, and offers of $17 to day found no buyers. The restriction of output is progressing, and will be continued until the accumulation of stocks has been absorbed. Trifling lots of foundry are moving for near-by requirements, but the tendency is decidedly downward. Bessemer iron is in moderate demand to meet Bessemer mill requirements. Muck Bars are quiet at $34.50@$35. Consumers of manufactured iron have pretty well supplied themselves, either by actual delivery, or by contracts for future delivery, at 2@2·10c.

The fact that there is enough merchant bar in stock to supply pressing wants, is giving tone to the market, and preventing any panicky demonstration on the part of buyers. Nails continue in good demand. Stocks are light and the tendency of prices is upward. Steel rail orders have been placed within a few days at $39.50. Old rails are quoted at $22 offered, and $22.50 asked. Scrap is without change.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, June 1.

Anthracite.

The slight symptoms of an improvement noticed in recent issues have again disappeared, and the market presents the features of extreme dullness. Buyers can not be induced to take a hopeful view of the future, and there is talk, probably with a view to stimulate the wavering, of putting up tolls all around on the first of July. The reports from the manufacturing interests throughout the East are discouraging, and while this demand is only a comparatively small factor, its falling off has the effect of making local dealers cautious. The avoidance of the strike in the Western iron mills dispels any hopes of increased business to the Eastern mills and gives prospect of a lively competition. Altogether, the outlook is not a very promising one at present, and interest therefore centers more and more upon developments in the West. The companies operating in that market should do their utmost to stimulate buying by low prices, because, after all, anthracite coal there is a luxury which is indulged in only when business is prosperous.

The Western Association met in this city this week. No change was made in the prices, and only points relating to the sales were discussed.

Bituminous.

The only current business is that of transient steamers, the manufacturing demand being low. There are rumors of low prices both at Georgetown and at Baltimore. We quote Clearfield, alongside, $4.10@$4.30; and Cumberland, $4.20@$4.35, according to quality.

STATISTICS OF COAL PRODUCTION.

Comparative statement of the production of anthracite coal for the week ended May 26th and year from January 1st:

THE enormous speculative dealings in wheat, cotton, and petroleum are attracting considerable attention and unfavorable comment. These paper transactions have assumed a volume that is absurd. The selling and buying, nominally, of nearly 350 million barrels of oil, 3 million bales of cotton, and 175 million bushels of wheat forcibly demonstrates the extent to which the gambling mania has taken hold of the public.

THE first installment of our report of the Roanoke Meeting appears in another column, a large part of it being the publication in full of President HUNT'S inaugural address, an able effort, which will be found to present a vigorous discussion of the means which engineers possess to meet the exigencies of the present period of depression. Some of Mr. HUNT'S suggestions will commend themselves to the consideration of manufacturers, notably his remarks on the labor problem, which is now so profoundly agitating the minds of all.

IN the course of a rambling paper, by Mr. W. S. SUTHERLAND, read before the Iron and Steel Institute, and an animated though equally aimless discussion, evidences appear that our British friends are beginning to devote some attention, in a mild way, to water-gas. For years, the English technical public has bestowed upon the new fuel that good-natured indifference which springs from a conviction of great superiority. Few have condescended to listen. There appears to be considerable confusion in the minds of British metallurgists on the subject, and the only fact of any real importance brought forward and sufficiently indorsed to be received without reserve is, that water-gas has done good work in connection with the welding of wrought-iron.

THE proposed meeting of the manufacturers of coke in the Connellsville District proved a failure, because the representation was not great enough to make the deliberations of such an assembly carry any weight. The rapid decline of prices is the result of a struggle the outcome of which leaves but little doubt. The market will not take all the coke, and it has become the question who is to stop producing. There are two classes of coke-producers, those having "drift" mines and those having "shaft" mines. The former are undoubtedly in the majority of instances fully capable of placing their product on the market at a lower price, and are "squeezing" their less fortunate competitors, who will not long be able to meet 85 cents per ton, on cars at oven, a price which must entail a positive loss of from 8 to 18 cents per ton. The latter are in favor of restricting the output, to strengthen the market and get at least a small share of the trade, while the drift men are not anxious to make concessions while they are in a position to dictate.

RECENT advices from England indicate that the basic process is making exceedingly rapid progress in Europe. During the six months ended with the close of March, 279,400 tons of basic steel had been produced by seventeen firms; one of them in England, one in Belgium, one in Russia, two in France, three in Austria, and nine in Germany, their output being:

	Tons.
England	57,911
France	5,962
Belgium	12,786
Germany	152,479
Austria	37,476
Russia	12,786

These figures, of course, are insignificant as contrasted with the duty of the acid plants in the United States, though they do not compare unfavorably with the work of the majority of mills working side by side with them in Europe. The only establishment actually working on a good scale is the Eston works at Middlesborough.

A PRELIMINARY summary of the report of Mr. BURCHARD, Director of the Mint, on the production of the precious metals, has been published, the figures presented being the following:

	Gold.	Silver.
Alaska	$150,000	.....
Arizona	1,065,000	$7,500,000
California	16,800,000	845,000
Colorado	3,360,000	16,500,000
Dakota	3,300,000	175,000
Georgia	250,000	.....
Idaho	1,500,000	2,000,000
Montana	2,550,000	4,370,000
Nevada	2,000,000	6,750,000
New Mexico	150,000	1,800,000
North Carolina	190,000	25,000
Oregon	830,000	35,000
South Carolina	25,000	.....
Utah	190,000	6,800,000
Virginia	15,000	.....
Washington Territory	120,000	.....
Wyoming Territory	5,000	.....
Total	$32,500,000	$46,800,000

This shows a decline of $2,200,000 in the production of gold and an increase of $3,800,000 in that of silver, a favorable showing, considering the many circumstances which have told against the prosperity of the mining industries.

PIG-IRON in the East appears to be approaching "bed-rock," to judge from the fact that furnaces are blowing out rapidly, and the iron ore miners have reached prices so low that no material reduction is probable. The forced restriction will tell on values as soon as surplus stocks in the hands of the weaker producers have been marketed. Many months have now passed by, and hardly any of the season contracts for foundry iron generally made in spring have been closed. Consumers have been buying strictly from hand to mouth, taking one-hundred ton lots at a time, and their stock of raw material must be exceedingly light. In regard to the manufactured goods which our foundries produce, the situation is not quite so favorable, and it may take some time before the surplus is worked off. On the other hand, we are approaching that period of the year when the demand is liveliest, and the work of distribution will soon begin. We can not help believing that the worst has passed. The process of getting down to the present more healthy condition has been a painful one, and much unjust and indiscriminating criticism has been heaped upon the shoulders of those who have led in the movement. The policy adopted has, however, undoubtedly been the

Digitized by Google

most judicious. It has placed the business on a sounder basis, and has contributed much toward bringing about a more speedy return to better times.

YEARS ago, in their eagerness to tap from the earth its hidden treasures of oil, drillers generally expressed disgust when nothing but gas rewarded their efforts. Later, some enterprising men began to turn their attention to this great source of caloric, and, one by one, a number of iron and glass manufactories in Pennsylvania carried the gas into their mills. They have not made much bluster over what they were doing, and have quietly pocketed the increased profits which their saving of fuel, due to the use of gas, has given them. Of late, however, the subject is attracting considerable attention in a quiet way, and recent developments indicate that the territory which may possibly be able to draw upon the new source of fuel supply is much greater than is generally believed. Gas-wells have been opened and are utilized as far west as Detroit and as far south as West Virginia, and Pittsburg is now getting excited over the extension of the business of the Murraysville well in Westmoreland County. Pipes have been laid down to a number of glass and iron-works in the eastern part of the great Smoky City, and a rapid extension of the field of the gaseous fuel is looked forward to. The belief is expressed by men whose opinion is worthy of much consideration, that the number of localities capable of being supplied with gaseous fuel in the States of New York, Pennsylvania, Ohio, West Virginia, and Michigan is much larger than the majority have any conception of, and the permanency of the flow of some of the older wells gives rise to the hope that it is a reliable fuel supply. Its cheapness and cleanliness are, of course, matters which are beyond all doubt. There are indications that during the present year a considerable number of companies will form to sink wells, and a "boom" is looked forward to that may bring forth the usual crop of unsound enterprises.

THE ROANOKE MEETING OF THE AMERICAN INSTITUTE OF MINING ENGINEERS.

The nucleus of the town of Roanoke was a small village known as Big Lick, situated at a point where a salt-lick originally attracted the wild animals of the vicinity. About this gradually grew up a village of ten or fifteen houses, with a small hotel and store. In 1881, the population was about 600. The building of the Shenandoah Valley Railroad to a connection with the Norfolk & Western, forming a great through route between the North and South, opened a new era in the economic history of the district. The town of Roanoke rapidly increased, until now it boasts of a population of nearly 5000, with about 600 houses, a new and comfortable hotel, and numerous industrial establishments. It is situated in the midst of a highly cultivated region, immediately at the junction of the Norfolk & Western and Shenandoah Valley railroads.

It was at this point that the American Institute of Mining Engineers decided to hold its regular summer meeting. The ride through the Shenandoah Valley is full of interest, and the scenery is grand and picturesque. The railroad first reaches the Shenandoah River at Riverton; thence it follows its general course for 120 miles. It then crosses a divide 1785 feet above tide between the Shenandoah and James river waters, and it follows the tributaries of the James River and the James itself to Buchanan, a distance of 50 miles or more; it then ascends another divide between the waters of the James and Roanoke rivers, and thence by the tributaries of the Roanoke to its junction with the Norfolk & Western, being for the entire distance in what is commonly known as the Valley of Virginia. During the late war, this valley was the scene of active military operations, and the railroad line passes through or near the battle-fields of Antietam, Shepherdstown, Winchester, Cedar Hill, Cross Keys, and Port Republic. The route abounds in points of interest, not only to the traveler seeking simply the picturesque and the beautiful, but also to the geologist, the mining engineer, and the iron-master; for the railroad follows closely the great Primordial ore-belt along the western flank of the Blue Ridge, which at many points has shown large and valuable deposits of rich iron ore.

It was expected, therefore, that this meeting of the Institute at Roanoke would prove very attractive. Already at least 125 members—many of them accompanied by ladies—have arrived, and others are still expected.

THE FIRST SESSION.

The first session of the Institute was held in the Roanoke Hotel, on Monday evening, June 4th. Addresses of welcome were made by Mayor Cocke, on behalf of the municipal authorities, and by Mr. I. B. Austin and Major Griffin, on behalf of the citizens. The words of greeting were specially cordial, and they were happily responded to by Mr. R. W. Hunt, the President of the Institute. The President then read his inaugural address, which was very favorably received.

THE PRESIDENT'S INAUGURAL ADDRESS.

Upon assuming the duties of the high position to which you have elected me, I beg to thank you most sincerely for the honor conferred. To be the presiding officer of your society is a gratifying distinction; but entering upon that office as the successor of the able gentlemen who have preceded me renders me diffident as to the results of the ensuing term. But believing your hearts, rather than your cooler judgments, were consulted in making your selection, I, in self-defense, now rely upon them for forbearing criticisms where weak, and warm support where strong and right. Connected as most of us are with the active industries of the country, we are called upon to encounter, not only engineering problems, but commercial ones as well. In fact, the two are so intimately associated, the success of one is the triumph of both. For while engineering difficulties may be overcome, if the result is not a commercial success, the world refuses to grant praise, and certainly withholds substantial rewards. I presume never since the organization of this Institute has the metallurgical engineer been called upon to meet a more embarrassing condition of affairs than at the present time. We have been through panics, through periods of depresssion and times of inflation; but just now, owing to the legislative status, an entirely new element enters into the problem.

After the warm words of graceful welcome to which we have just listened, with the certainty of having displayed to us, during the next few days of our visit to their store-house of nature's treasures, such boundless mineral and agricultural wealth, made available by intelligent enterprise and industry, it is next to impossible to realize the existence of aught but untrammeled prosperity. Eight years ago, the President of this Institute, in his address at the Cleveland meeting, presented as he so well could, and in his clearest, most forcible manner, the necessity for a general adoption of better methods, more economical machinery and saving appliances in all branches of manufacture. His warning words were uttered at a time when the business outlook was much the same as now. During the years which have lapsed since then, many steps have been taken in the right direction. But a period of great prosperity, at least of great activity, came upon us. Nature's refreshing rains and glowing sunshine made our fertile plains rich with golden harvests. Thousands from foreign shores came to us, seeking new homes in our God-blessed land. There has been work for all, plenty for all, demand for every thing. The result was a feverish state of drive. Did the blast-furnace have a daily output of sixty tons, alter the lines—put up new stoves—another engine—force it—blow it—better still, build another and bigger one—produce two hundred tons per day! The Bessemer works were designed for and expected to make fifteen hundred tons of ingots per week. Put on three sets of hands, let the week of production begin on Sunday afternoon; the week of labor never end; and then, not be content with a weekly yield of three thousand tons. This has been the hot-blooded life of the past few years; but following it, have we not sometimes neglected true economy? If not, then well. But whether yes or no, the time is now here when we must have cheapness of production as well as quantity. I take it, no matter what may be our views on the subject of protection, the supreme duty of every engineer is to aim at placing our industries entirely independent of the whole subject. An easy statement to make—not so easy of accomplishment. But our duty remains the same. How can it be done? Most emphatically not by placing American labor on the same basis as foreign; not by employing women and children to perform the work not of men alone, but that of beasts of burden; not by giving our workers hovels instead of homes; not by depriving them of wholesome diet; not by rendering education and advancement all but impossible; not by breaking down the barriers of morality; not by making the united efforts of a skilled man, his equally skilled wife and daughter, capable of yielding but $5.13 per week! I am proud to believe the reduction of labor to this point would require a plant for the construction of which the average engineering mind is incapable. Unfortunately, when pinching times afflict us, when the necessities of curtailment of costs arise, we at once attack the wages problem as the certain and only way of salvation. That point of reduction of cost is so easily reached. Understand me; I do not mean that labor should not bear its share of depression, as it certainly always will of prosperity. But if we would give deeper thought, and not permit the human proclivity for hitting some other body satisfy us, we should make greater and more lasting savings. You may make a heavy reduction in wages, and save but a small amount per ton of product; and when times change, the reduction must be restored. But save a few per cent of loss in the processes of manufacture, and your aggregate is the same, and that reduction in cost remains permanent. By the difference between an unintelligent, careless, and indifferent use of the non-producing supplies in one engine and its train of rolls and a conscientious effort at economy, an actual saving of one hundred dollars per month has been possible. This is not a fortune; but if you have say forty engines and thirteen trains of rolls, it merits respectful consideration. Better let that master mechanic's wages remain at a fair standard and have him save for you, than to take from him and let another lose for you. Hence, I argue that the first duty is seeking after better methods, then a rigid and economical administration, and *then* a revision of the whole labor question. I think my statements as to not favoring a descent to the level of foreign labor have been sufficiently strong; but at the same time, I claim that the relative pay of our workers is not properly balanced. The machinists, the pattern-makers, the carpenters, the mechanics of America have to serve an apprenticeship of from three to four years, receiving during that time not more than enough to pay their board. After learning their trades, they can not hope for, in fact are satisfied with earning from two dollars and twenty-five cents to three dollars per day, the latter being for exceptionally skillful workmen, two dollars and fifty cents per day being about the average. Should these men develop sufficient talent, they may become foremen, at say $100 per month. Their employment demands physical skill, patient toil, frequently fearless exposure to physical danger, and a certain amount of intellectual education. The greater the latter, the more certain is the possessor of constant employment and success. From the daily wages stated, it of course follows that the yearly earnings are moderate. Nevertheless, in all manufacturing communities of this country, you will find that the mechanics are, as a rule, the men who have acquired homesteads, who live with the most comfort, and whose children are prepared for a higher plane than that occupied by their parents. It certainly seem unjust that, as opposed to such a class of workers, other men without intellectual education, with trades that, with scarcely an exception, if sufficient physical strength is possessed, can be acquired in less than a year, should control a rate of pay from one and a half to three times as great. The young man in the machine-shop cheerfully devotes his time, while learning his trade, for a compensation of some three dollars per week. His fellow in the rolling-mill, if over eighteen years of age, must receive from a dollar and a half to two dollars per day, or he will remain in idleness. To my mind, true justice demands that the wages of the skilled mechanic should be the basis in comparison with which the rate of all other labor should be determined. But to reach the sought-for plane, to place the manufacturers of this country in a position to compete in the open markets of the world, to render the question of tariff entirely one of revenue, one more

Digitized by Google

thing is absolutely necessary: We must have cheap raw materials. No matter how much engineering skill is exercised, no matter how economical the administration, no matter how low the rewards of labor, unless the coal, the ore, the pig metal, are obtained at a far lower price than we now know, our market must be limited to our own domain, and the foreign importer must be handicapped by an impost; or else our furnaces must remain cold, our mills idle, and the mines of either my own New York or those of hospitable Virginia lie undeveloped.

To give us this cheap material, other than labor must be content with smaller returns. If the ore property is acquired for say fifty thousand dollars, the company formed to develop it must not have a capital of a million, and each stockholder expect at least ten per cent on his watered investment. I fully appreciate that this is not likely to be received with favor; but if the demand is for steel rails at about twenty-five dollars per ton, to meet it the manufacturers must have pig-iron at the English price of say from twelve to thirteen dollars. Then, with the American converter, averaging 42,705 tons, against 20,920 for the English, and 15,001 tons for the French per year, there need be no fear but the American product can compete in any market, and at the same time pay labor as American labor should be rewarded. It has been demonstrated that freight can be carried over our railroads, and profits made, at a rate per mile that a few years ago seemed impossible. Our country is one of long distances. The various raw materials are generally far apart, or else the market is distant. Hence railroad engineers and managers have already contributed their share toward solving a problem which, view it as you may, is one of at least not easy solution. The bounden Christian duty of every one, in whatever sphere he may be placed, is to properly administer the talents given unto him. The seeking after the best methods in all things is imperative on all. But have we not cause to be proud of the development of our country, and reasonably well satisfied with the results? Coming, as we distant members of this Institute do, to partake of the hospitality and witness the Aladdin-like achievements of our hosts of this section of Virginia, are we not inclined to conclude that the system which has rendered such things possible is fit to live? If so, then, gentlemen, we must resort to political as well as engineering methods.

The advisability of such a policy has been recognized by at least one association of capitalists. The furnaces and mills located on the Hudson River, while possessing many advantages of location, have been handicapped by high-priced fuel. This must ever remain—and in the struggle of the survival of the fittest, there could be but one other element to offset this disadvantage. If cheap and good ore could be obtained, the distance from the coal-fields would be more than neutralized. To Mr. James A. Burden, of Troy, belongs the credit of a methodical investigation, rewarded by complete success, which promises to make the Hudson Valley one of the most favorable points for the production of cheap and good iron in the United States. The gentlemen associated with Mr. Burden in the possession of the Hudson River ore property, and also the Chateaugay property, believe that their true interests point toward a large output at a small profit. Fortunately, the mixture of the Chateaugay and Hudson River ores in about equal proportions furnishes an easy working burden, and yields good foundry, mill, and Bessemer irons.

Taking Troy as a point at which these ores may be brought together and smelted in properly constructed furnaces, costs can be figured about as follows:

1 ton of Chateaugay 1 ton of Hudson River	$6.50
1¼ tons of coal	5.00
Limestone	.50
Ore, tools, etc	.50
Labor	1.50
Repairs, etc	1.00
	$15.00

If Mr. Burden's policy is adhered to, it would seem as though hope still exists for some of us.

Papers were afterward read by Mr. A. S. McCreath on the Iron Ores of the Valley of Virginia, which we print in this issue, and Capt. C. R. Boyd on the Ores of Cripple Creek, Virginia.

On Tuesday morning, a visit was made to Lynchburg, on a special train, provided by the courtesy of the Norfolk & Western Railroad. Here the Lynchburg blast-furnace was visited.

THE LYNCHBURG BLAST-FURNACE.

The stack is 60 by 12 feet 6 inches. It has four tuyeres with 4½-inch nozzle. The blowing-engine has a steam cylinder 20 inches in diameter, with four-foot stroke, and a blowing-cylinder 60 inches in diameter, with four-foot stroke. The engine was built by the proprietors of the furnace, Messrs. Carter & Stevenson. The ores used are chiefly brown hematites, mined along the line of the Richmond & Alleghany Railroad. They yield an average of about 47 per cent metallic iron. The fuel used is Connellsville coke. The furnace produces 35 tons daily of soft foundry iron.

THE RIVERVILLE IRON MINES.

A visit was then made to the iron mines on the James River near Riverville, a special train having been kindly furnished by the Richmond & Alleghany Railroad. The mines visited are located at a point about two miles from Riverville, and twenty-four miles northeast of Lynchburg. The ore is of the specular variety, and may yield from 45 to 50 per cent metallic iron, with the phosphorus sufficiently low to make it suitable for Bessemer pig-iron.

At Riverville, an excellent collation was provided by the citizens of Lynchburg, whose guests we were for the day. After the wants of the inner man had been satisfied, a few speeches were made, cordially welcoming the members of the Institute. Numerous points of interest were afterward visited in Lynchburg, notably the Chamber of Commerce, where a fine exhibit of different kinds of minerals was displayed. We returned to Roanoke in the evening, too late for a second session, which had been arranged to be held at Lynchburg, but which was unavoidably omitted.

To-morrow (Wednesday) will be spent visiting points of interest around Roanoke, including the new furnace of the Crozer Steel and Iron Company, the Roanoke Machine-Works, and several iron ore deposits in the immediate neighborhood, which will be fully described hereafter.

ROANOKE, VA., June 5, 1883.

THE RAILROAD EXHIBITION AT CHICAGO.

Special Correspondence of the Engineering and Mining Journal.

The Exhibition is now thoroughly under way, and is attracting attention of a character to meet the most sanguine expectations of its managers. The time having been extended until the evening of the 5th in which to complete exhibits, there has been considerable activity among exhibitors to make the best display possible. In variety and character of exhibits there is every thing to be seen which is of interest, not only to the railroad man, but to many who are engaged in kindred and allied mechanical pursuits, The visitor may profitably pass two or three days in the exhibition building, and then depart without having done full justice to the many novel details of railroad construction now brought forward. The attendance has not yet developed much of a railroad character. Next week will, however, witness a large influx of this class, who will express no little praise at the novelty of concentrating under one roof so much in which they are specially concerned.

It may afford your readers some satisfaction to learn who among the numerous exhibitors are enterprising to the extent of meeting the best attention. Among locomotive-makers, first and foremost in its display, I may allude to the Brooks Company, of Dunkirk, N. Y., which has four of its engines in the Annex that attract marked attention. The Philadelphia & Reading Coal and Iron Company has a handsome engine, No. 372, of its own make, possessing special features. The engine is said to accomplish work not in the reach of many of its kind, and boasts of very high records. Other manufacturers have their engines on exhibit, which in all make a most creditable appearance in this line. The Brown Hoisting and Conveying Machine Company, of Cleveland, Ohio, has on exhibit its machine on a tramway, which enables it from time to time to practically illustrate its workings to the visitors who admire its simplicity in the execution of its work. Creaser, Adams & Co., of Chicago, have a large booth located in the center of the building, in which are displayed the various fixtures adapted to railroads, mines, etc. Fairbanks, Morse & Co. have an immense tank supplied with water by an Eclipse wind-mill, one of the prominent features of the exhibit. That live house of St. Louis, M. M. Buck & Co., has a handsome exhibit of heavy railroad and engineer's supplies, and Keuffel & Esser, of New York, are prominent by the fine character of their engineering instruments and supplies; they display a full line of such articles as enter into the wants of engineers, among which are many specialties controlled by them.

In minerals, ores, and the like, there is a very fair display from the Lake Superior and Northern country. The success of the electrical railroad may now be considered assured.

A COMPARISON OF THE WORKING OF A BLAST-FURNACE WITH BLAST VARYING IN TEMPERATURE FROM 990° FAHR. TO 1414° FAHR.*

By W. Hawdon, Middlesborough.

(*Concluded from page* 317.)

In order to ascertain if the temperature of the escaping gases was affected by the increased temperature of the blasts, tests were made over a period of twelve hours, and taken every fifteen minutes or thereabouts. The temperature of the escaping gases varies so much over any given period that a test taken at random, or even over a couple of hours, is very misleading. The time of lowest temperature is, of course, when a large amount of material has been charged into the furnace. This, in the course of ordinary working, is as low as 323°, and gradually increases during the time that charging operations are suspended. The results of trials taken throughout the day, October 31st, 1882, when the average temperature of the escaping gases was 490° Fahr., show that the average temperature of blast was 1065° Fahr. As the rise in temperature is gradual after charging has ceased, the trials were not so frequently made, but that is allowed for in taking the average temperature.

The temperature of the gases was taken in a similar manner over twelve hours on other occasions, showing:

	No. 1.	No. 2.
Average temperature of gas	468° Fahr.	448° Fahr.
Average temperature of blast	1139° Fahr.	1493° Fahr.

From this it would appear that the temperature of the escaping gases decreases with the decrease of fuel, although this decrease of fuel is compensated for by an increase of blast temperature.

The volume of the escaping gases is smallest when the higher temperatures of blast are used, since, when this is the case, the amount of fuel consumed is smallest, and consequently the amount of air blown in to consume this fuel is smallest. The weight of gas per ton of iron we find to be 133·3 cwts., when the blast is 1376° Fahr.

The volume of the escaping gases is largest when the blast temperature is low, since, when this is the case, the amount of fuel consumed is larger, and consequently the amount of air blown in to consume this fuel is also larger. The weight of gas per ton of iron we find to be 140·8 cwts. when the blast is 990° Fahr.

In both cases, the gases, in passing up the furnace, pass through the column of material, namely, coke, mine, and limestone, which is charged at the top of the furnace.

The materials, in passing down the furnace, absorb practically the same amount of heat in both cases. But since the volume of the escaping gases in one case is less than the volume in the other, the temperature of the gases when they are leaving the furnace will be lower when the volume is small than when it is greater, granting, at the same time, that the furnace is of sufficiently large capacity to allow of absorption with the quicker driving—that is, when the gases are passing off more rapidly.

In order to ascertain how much of the iron-stone remained uncalcined after it had passed through the calcining-kilns, samples were taken in bulk in the following manner: Three shovelfuls of mine were taken from each of the six openings of the kilns, and the whole thoroughly mixed. This operation was repeated at each kiln. About one quarter of the mine from each kiln was taken for sample and thoroughly mixed together. This was crushed in a mortar-mill, and a sample taken to the

* Read before the British Iron and Steel Institute.

Digitized by Google

laboratory. An average of five such samples of calcined stone, as determined by Mr. Stead—to whom I am indebted for the analyses given in this paper—gave the result:

	Per cent.	Cwts. per ton.	Oxygen.	Carbon.
Fe_2O_3	49·38	24·01	7·20	....
FeO	4·72	2·30	0·51	...
CO_2	2·98	1·45	1·06	0·39
Loss by calcination	3·11	1·51	....	....
SO_3	0·66	0·32	0·19	....
	....	....	8·96	0·39

This gives metallic iron = 38·13 per cent.

The CO_2, of course, passes off at the top of the furnace, and affects the calculation in computing the weight of carbon which passes down to the tuyeres. It is therefore necessary, in computing the value of the gases, to make the allowance for this uncalcined stone.

The unburnt stone is chiefly found in the center of the large lumps, and although the stone may appear almost perfectly calcined, yet in the best-constructed kilns from 2 to 3 per cent is generally found to be the further loss when a sample taken from the kilns is submitted to perfect calcination in a muffler. Samples were taken from the kilns at two other works in Middlesborough, when the stone was well burnt, and gave a further loss of 1·8 and 2·8 per cent respectively.

The practical work accomplished in this furnace by increasing the temperature of the blast from 990° Fahr. to 1414° Fahr. has been a saving of 1¼ cwt. of coke per ton of iron, and an increase in make of 60 tons per week, with a better quality of iron by nearly one fourth of a grade, and that, too, without any increased reduction of silicon into the iron, though it would appear that rather more limestone is required when the higher heats are used.

It becomes now an easy matter to calculate whether it is worth while pulling down old pipe-stoves at any particular stage of wear and tear, and replacing them with the effective brick-heating stove of the Cowper, Whitwell, or similar type.

A very important item in connection with the working of brick regenerative stoves in place of the ordinary U-pipe stove appears to have escaped general observation. I refer to the amount of gas required to heat the blast by this method.

The pipe-stoves in use at the Newport Iron-Works are of modern construction, and may be taken as among the best of the kind. There are nine to each furnace, eight of which are at work while one is off for cleaning purposes. Each stove has twelve pipes, with a heating surface of 100·48 square feet per pipe = 1205·76 square feet per stove, giving $8 \times 1205{\cdot}76 = 9646$ square feet of heating surface per furnace.

The cubical contents of each stove = 1781 feet. That of the pipes in each stove = 320 cubic feet, which, deducted from the former, gives 1461 cubic feet in each stove to be filled with the gases in combustion. This gives $8 \times 1461 = 11{,}688$ cubic feet per furnace. Therefore the proportion of heating surface of the pipes is to the cubical capacity of the stove as 9646 square feet heating surface : 11,688 cubic feet capacity of stoves, or as 1 : 1·21.

Now in the Cooper stoves, which are at work at this furnace, one working the blast while the other is heated with the gas, there are 42,860 square feet of available heating surface per stove.

The cubical capacity of each stove is	18,610 cubic feet.
That of the brick is	8,406 "
Difference	10,204 "

Therefore the proportion of heating surface is to the cubical area as 42,857 square feet : 10,204 cubic feet, or as 4·2 is to 1, as against 1 : 1·21 in the other case, showing a great economy of space to be filled by gas under combustion in the brick stove. And moreover, the outside surface of the brick stoves is much less than that of the pipe-stoves, giving thereby less surface for radiation. In the pipe-stove, there is not a sufficient length of time, nor is the surface of the pipes of sufficient area to allow of the complete absorption of heat from the burning gases. But the gas which is ignited at the bottom passes rapidly and directly through the stove and out of the chimney at the top, where it escapes at the high temperature of 1240° Fahr.; while with a well-designed brick stove, the gas has a long way to travel, a large surface of bricks to pass over, travels at a much slower rate than is the case in the pipe-stove, and consequently the heat is so thoroughly absorbed by the bricks that the gases escape into the chimney at a temperature (from the Newport stoves) of 250° Fahr.

The escaping gases analyze as follows:

	From the pipe-stoves.	From the Cowper stove.
N	74·24 per cent.	74·75 per cent.
CO_2	24·30 "	24·15 "
CO	Nil "	Nil "
O	1·46 "	1·10 "
H	Nil "	Nil "
	100·00	100·00

Showing in both cases very little excess of air.

In order to ascertain the amount of gas passing through the various flues to the stoves, boilers, etc., readings were taken by Swan's tube anemometer, with the result that the sum of the amounts passing down the gas tubes from the two furnaces in blast showed only an excess of 3·6 per cent over the sum of the amount passing into the various stoves and boilers, thus showing comparative accuracy in the readings. The anemometer showed exactly the same amount of gas passing down the gas tube from each furnace.

The pipe-stoves at work on the No. 6 furnace are identical with those formerly at work on No. 8. One of them was off for repairs, and one cleaning, leaving seven at work.

Taking the sum of the amounts of gas passing down the two gas tubes as unity—they being the source of supply—we have—

To the Cowper stoves	14·9 per cent.
To the seven pipe-stoves	23·4 "
Through the gas-flue to the boilers	61·7 "
	100·0

Now we find that the gas per ton of iron passing from No. 8 furnace = 133·3 cwts., the anemometer reading being taken at the same time, giving at the rate of 266·6 cwts. per ton passing from the two furnaces as our gas supply. The sum of the two amounts = at the rate of 266·6 cwts. gas per ton of iron to each of the set of stoves which respectively supply one furnace; but in the case of the boilers, the number of tons is at the same time doubled, the steam supply from the boilers being to both furnaces, the make at the two furnaces being nearly the same.

This gives us—

	Cwts. gas per ton of iron.
To the Cowper stoves	39·63
To the seven pipe-stoves	62·25
Through the gas main to boilers	164·12+2
	266 cwts.

Taking first the Cowper's stove. From the gas analysis, 27·34 per cent is CO = 11·71 C. This per cent of 39·63 cwts. = 4·64 cwts. carbon. Hence we have developed:

	Cwts. heat units.
(CO to CO_2) $4{\cdot}64 \times 5600$	= 25,984
Hydrogen	= 1,056
Sensible heat of gas, $39{\cdot}63 \times 102° \text{ C} \times {\cdot}24$	970
	28,010

We have carried out heat units from—

		Heat units.
Blast ($746° + 42°$ loss from stove to tuyere)	= $788° \text{ C} \times 98{\cdot}17 \times {\cdot}237$	18,333
From waste gases	39·63 cwts.	
Add weight of air required to consume 4·64 cwts. C from CO to CO_2 and 0·03 cwt. H, and due to 1·1 per cent excess of O in waste gas	29·24 "	
	68·87 "	
$68{\cdot}87 \times 140° \times {\cdot}24$		2,313
Leaving for radiation		7,364
Total		28,010

Take now the pipe-stoves: 11·7 per cent of 62·25 cwts. = 7·28 cwts. carbon. This develops (CO to CO_2)—

	Heat units.
$7{\cdot}28 \times 5600$	40,768
Hydrogen	1,700
Sensible heat in gas, $62{\cdot}25 \times 102 \times {\cdot}24$	1,523
	43,991

We have passing out—

	Heat units.
Blast, 531° C × 105 cwts. × 237	13,960
Waste gases ($62{\cdot}25 + 49{\cdot}9 = 112{\cdot}15$ cwts. × 671° × 24)	18,061
Leaving for radiation	11,970
	43,991

In this latter case, 105 cwts. of blast is taken as used, as is the case with the lower temperature of blast.

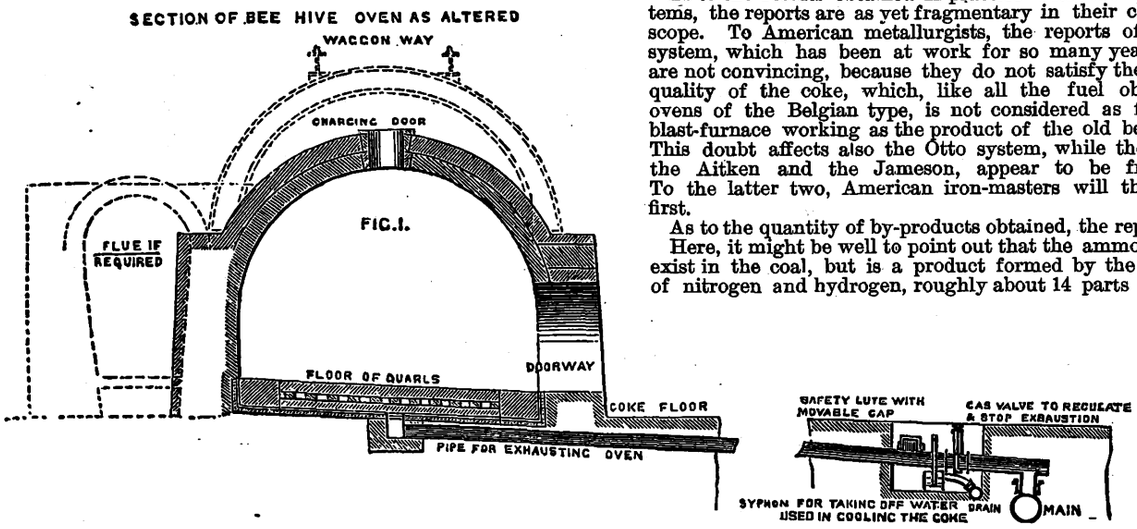
The difference ($62{\cdot}25 - 39{\cdot}63$) = 22·62 cwts. gas per ton of iron, represents the amount of gas saved by using the brick stove in preference to the pipe-stove, and might, with proper application, be used for calcining the iron-stone, where that is necessary, or for other purposes.

Now 22·62 cwts. is 16·9 per cent of 133·3 cwts.; or, in other words, the saving effected by heating the gas in the brick stoves is equal to 16·9 per cent of the whole of the gas given off from the furnace. Of this 26·3 per cent is CO = 6 cwts. CO per ton of iron, which, when burnt to CO_2, gives $2{\cdot}57 \text{ C} \times 5600 = 14{,}393$ cwts. heat units.

The calorific power of the small coal used in the Cleveland District for calcining purposes may be taken at 7000; so that if this heat were applied to calcine the iron-stone, it would represent $\frac{14{,}392}{7000} = 2$ cwts. (about) of small coal per ton of iron made. At the Newport Works, we use 2¼ cwts small coal to calcine the iron-stone required to make one ton of iron. At some works with high kilns, as small an amount as two cwts. is required. A certain amount of this, doubtless, passes off burnt to only the first degree, or CO. Therefore, we find that the saving in gas by using the brick stove is about the quantity requisite to calcine the iron-stone for use in the furnace. The ordinary type of calcining kilns is without doubt unfitted for this mode of firing; but it does not appear unlikely that kilns can easily be adapted for the purpose. A great advantage is found in using the brick stoves during the prevalence of high winds, owing to the better draught of the chimney, when, as every furnace manager knows, it is impossible to maintain the heats with the ordinary type of U-pipe stove. We may therefore congratulate the inventors of brick regenerative stoves on having introduced an improved mode of heating the air, though the advantage, when compared with the cast-iron pipe-stoves, where the services they render give such fair results as from 1050° to 1100° Fahr. of blast temperature, is not, according to our experience, equal to that which has in some instances been claimed for them. As an instance of the saving effected, we will take the No. 8 furnace at Newport Works; the Cowper stoves are built of best Wortley fire-bricks, and the whole workmanship is of the best quality. They cost £2200 each = £4440 per furnace, without the foundations, which were already in; and the chimney, which is large enough to drive stoves for three furnaces, cost £270.

	Per year.
Interest and depreciation on the Cowper stoves at 15 per cent	£700 0 0
Interest and depreciation on the pipe-stoves at 15 per cent	495 0 0
Difference	£205 0 0
Saving in coke, as in the Newport case, 1⅛ cwt. per ton = 11¼d. One fourth better grade in quality = 3d. per ton. Total saving, 14¼d. per ton. On 400 tons per week, say, 20,600 tons per year	£1,223 2 6
Deduct	205 0 0
Total saving per annum in favor of the brick stoves	£1,018 2 6

There remains, in addition, the saving of gas, which, if properly applied, is no inconsiderable item, and the profit—when such a desirable result is accomplished—on the extra make.



AT a recent meeting of the Engineers' Club of Philadelphia, Percival Roberts, Jr., exhibited a turning from a cast-steel roll. The dimensions of the roll, which was cast from open-hearth steel, were about 30 inches by 5 feet 6 inches. The turning is 4 inches wide by 12 inches long, 1¼ inch thick, showing the roll to have been very homogeneous for cast-steel.

UTILIZATION OF BY-PRODUCTS IN THE MANUFACTURE OF COKE.—III.

The Jameson System.—The latest claimant for attention in the recovery of the volatile products in coking is J. Jameson, who also attempts only a modification of the ordinary bee-hive oven, and whose particular aim appears to be to keep the coking process precisely the same as in the old plan. Mr. Jameson rejects the use of the fuel-gas remaining after the tarry and ammoniacal products have been condensed, on the ground that the heat which can be generated by the burning of this waste gas, being previously cooled, is not sufficiently high, compared with that obtainable by burning a part of the carbon of the charge. He says also that the portion of the coke formed at a low heat in a comparatively cool fresh-charged oven is inferior in quality to that produced at a higher heat at a later stage of the coking.

Figs. 1 and 2 show a sectional elevation and plan of the Jameson oven,

from which it will be seen that, in place of being solid, the floor is perforated by numerous holes formed in fire-clay quarls, a suction-pipe of cast-iron being inserted so as to communicate with the openings. It is important to have a secure and tight foundation, in order to avoid drawing air and vapor from the surrounding ground; and this is accomplished by placing a double layer of bricks set in hard pitch at such depth below the actual floor as not to be exposed to undue heat. In building new ovens, it is also considered advisable to lay one or two damp courses of slate and tar, such as are used in house building, over the whole surface of the foundation. The oven is charged as usual; and when well ignited, a slight exhaustion is applied at the bottom through the pipe previously referred to, so as to remove a portion of the nascent products of distillation, instead of allowing them to pass up through the ignited portion of the charge. The suction should be equivalent to about 200 cubic feet of gas per hour per ton of coal in operation, but must, however, vary somewhat with the quality of the coal, some coal being more rich in gas than others. The amount of suction capable of being applied should be about three inches of water; good results have been got with about half an inch; but for resistance in the scrubber and a margin for seals, the power available should not be restricted to that in the first instance. The suction, beginning as soon as the oven is well ignited at the top, should be continued for at least sixty hours for a five-ton oven, although the charge may before that time be ignited throughout, there being still a yield of oil apparently re-distilled from the oven bottom. It is considered best to employ for suction such apparatus as a Root blower, or an exhauster of the Beale pattern, the delivery of which will vary nearly as the speed, as there is, of course, one rate of suction most favorable with each kind of oven and species of coal operated upon, and this should be secured as nearly as possible.

The temperature of the gas as it leaves the ovens averages about 180 degrees Fahr.; and as, in order to obtain the best results, it is important to condense as much as possible, it is recommended that very efficient cooling surface should be provided. If cold water is available at moderate cost, it is of value, especially in extracting the last traces of the more volatile products, bearing in mind that, contrary to the usage of gas-works, it is in this process desirable to take from the gas as much condensible matter as possible. By tapping the condenser at different hights, a certain separation of light and heavy oils may be obtained, which is valuable when dealing with large quantities. Probably the best method of obtaining the separation is by the process of fractional distillation now worked by Messrs. H. L. Pattinson & Co., at Felling, by which liquors of five or six different specific gravities can be automatically run into separate receiving-vessels. This process simply consists in providing discharge-lutes at so many places in the condensing-pipes, the more easily condensible constituents being run out of those nearest to the ovens, and the more volatile parts at a later period when the temperature has been still further lowered. Finally, the gas is passed through a dry scrubber, and may then be used for heating purposes, for working gas-engines, or for illuminating in connection with burners, such as the Lewis & Clamond, in which light is obtained by the incandescence of platinum or some other artificial medium instead of from the carbon contained in the gas. In some cases, the residual gas might be of greater value for concentrating the ammonia-water, which, on first condensation at the ovens, is large in quantity, and therefore costly to transport.

As to the results obtained in practice with the different systems, the reports are as yet fragmentary in their character and scope. To American metallurgists, the reports of the Carvès system, which has been at work for so many years in France, are not convincing, because they do not satisfy them as to the quality of the coke, which, like all the fuel obtained from ovens of the Belgian type, is not considered as favorable for blast-furnace working as the product of the old bee-hive oven. This doubt affects also the Otto system, while the two others, the Aitken and the Jameson, appear to be free from it. To the latter two, American iron-masters will therefore turn first.

As to the quantity of by-products obtained, the reports vary.

Here, it might be well to point out that the ammonia does not exist in the coal, but is a product formed by the combination of nitrogen and hydrogen, roughly about 14 parts by weight of the former to 3 of the latter. The whole of the nitrogen existing in the coal is not, however, converted into ammonia, although there is always more hydrogen present than would be necessary for this total combination. Only a portion is thus utilized, part of the remainder escaping unaltered, while some part clings to the coke, and a small fraction combines with carbon to form cyanogen. This matter was fully treated in a paper read by Professor Forster, M.A., F.C.S., before the Chemical Society of London, last December, and we understand that still further investigations are now in progress.

Mr. Henry Simon reports that at Bessèges nearly 3 cwts. of ammoniacal water and 72½ pounds of tar are obtained per ton of coke. In preliminary work with the Otto system at Wattenscheid, Germany, the quantity of tar obtained ranged between 3·13 and 3·90 per cent of the weight of the coal, while the value of the ammoniacal water averaged 10·93 marks on a coal which was worth 60 marks per ton at the pit's mouth. Mr. Aitken got 11 gallons of oil per ton, and 30 gallons of water, containing in one test ammonia equivalent to 9·7 pounds of sulphate of ammonia per 100 gallons of water. Mr. Jameson reports that with Shiremoor coal, 13 gallons of crude oil, and ammonia equal to 9·87 pounds of sulphate, were obtained per ton of coal; while with Longhirst small, 9·28 gallons of oil, and ammonia equal to as much as 17·78 pounds of sulphate, were recovered. With fractional distillation, the results are especially interesting, and the following is given as a sample experiment with one charge:

Number of delivery-pipe.	Quantity collected.	Specific gravity.	Remarks.
	Gallons.		
1	5·00	1·015	Contained 18·6 per cent of water, and a great quantity of scale paraffine.
Close to oven	9·87	·990	Contained 1 per cent of water.
2	7·70	·980	Contained 10·4 per cent of water.
3	2·00	·945	No water.
4	6·00	·960	Contained 1 per cent of water.
Dry scrubber			

Altogether, the ammonia in this charge was equal to 12·2 pounds of sulphate per ton of coal.

ORE-DEPOSITS OF SUMMIT DISTRICT, RIO GRANDE COUNTY, COLO.*

By R. C. Hills. Condensed for the Engineering and Mining Journal, by S. F. Emmons.

The Summit District, which is situated near the summit of the San Juan Mountains, to the west of Alamosa, and south of the head of the Rio Grande above Del Norte, is famous for the remarkably rich gold deposits of the Little Annie and other mines. Mr. Hills's paper, which is too voluminous to be presented in full in these columns, is devoted to a consideration of the geological relations and genesis of ore-deposits of this region, and is based upon extended examination, and chemical investigation conducted by himself.

His views are, briefly, that the vein-like forms of auriferous quartz constituting these deposits have resulted from alteration and mineralization of an eruptive rock by solutions circulating along a contact plane; that subsequent folding and erosion gave rise to the existing series of parallel quartz bands, which have much the appearance of true veins.

In the accompanying diagrams, Fig. 1 shows the relative position and the sinuous course of the outcrops of the various rocks and the so-called veins. Fig. 2 is an ideal section along the line *a b*, illustrating the manner of folding and the number of plications.

The ore-deposits are principally confined to the northern and eastern slopes of South Mountain. The rocks of the region are all eruptive, and belong to the middle of what he calls the Tertiary eruptive series of Southern and Western Colorado. Those exposed in the immediate vicinity of the mine occur in the following order, beginning with the oldest:

1. *Andesite*, of dark green or black color.
2. *Granular rhyolite*, with large twin crystals of sanidine, and granules of quartz, biotite, hornblende, and apatite.
3. *Trachyte breccia*, not always present in cross-section.
4. *Andesitic trachyte*, with large crystals of sanidine and biotite, and a ground-mass composed mostly of plagioclase.
5. *Black rhyolite*, constituting a semi-vitreous ground-mass, with crystals of sanidine and biotite.
6. *Gray andesitic trachyte*, the most recent rock exposed in the district.

The aggregate thickness of these rock does not exceed 300 feet.

Horizontal pressure, acting in a northeast and southwest direction (that of least resistance), has produced six complete folds and a series of minor undulations. Similar pressure, acting at right angles, or in a northwest and southeast direction, has caused a further plication, which is shown in the sinuous course of the outcrops.

As shown in the section, the apexes of all the folds have been removed by erosion; the only exception being that of the Columbia-Treloar fold where the quartz apex still remains on the Golden Queen claim. These folds are shown sometimes in natural cross-section, as in the Bobtail and Major, and at other times by tunnels driven at right angles to the course of the veins. The metalliferous quartz bands are conformable with the folded strata, and occur along the plane of contact of the granular rhyolite with the breccia or with the andesitic trachyte, when the breccia is absent. The thickness of these silicified bands varies from three to thirty feet, being much greater when, by the folding process, two or more layers of quartz are forced into contiguous position.

The quartz bands, which correspond to the ground-mass of the rhyolite, are usually of compact structure. The quartz granules of the original rock may still be detected in the compact matrix, while the large crystals of sanidine, so conspicuous in the unaltered rhyolite, have for the most part disappeared, although their former existence is indicated by the numerous cavities still retaining the form of the feldspar. In some cases, pseudomorphs of quartz after the Carlsbad twins occur, but mica has entirely disappeared. The ore consists of auriferous pyrite and enargite, with their oxidation products. As accessory minerals are sphalerite and galena, and occasionally native sulphur.

The zone of oxidation to which all the more valuable bonanzas thus far discovered are confined is of varying depth, reaching a maximum of 300 feet. In the Little Annie and Little Ida claims, which are on the same plane, gold is most abundant near the center of the band; sometimes, it consists of innumerable small grains, so closely aggregated as to appear like a continuous sheet of metal. At the actual outcrop is the zone of impoverishment, which extends down to a depth of 50 feet or more, in which the quartz, while slightly impregnated with oxide of iron, is not sufficiently auriferous to constitute valuable ore. As an exception to this rule, in the Little Annie and Major claims, the oxidized ore at the surface is extremely rich; in the former, it is colored reddish-brown by oxide of iron, and often contains barite. Gold is mostly confined to fracture planes containing oxide of iron, and is found occasionally in dodecahedral crystals a millimeter in diameter. Near the ore-bodies, the decomposition has progressed more or less in the country-rock; and in their immediate vicinity, the feldspars are completely altered to kaolinite. Traces of lime or potash are seldom obtained from these decomposed rocks, and biotite is invariably altered to white potash-mica or muscovite. Kaolinization is not confined, however, to the immediate vicinity of the bonanzas, but is taking place on a large scale in districts at considerable distance from the ore-bodies.

In the Missionary and Golden Star claims, are two vertical veins running about north and south, which traverse the andesite and granular rhyolite, and connect with the quartz band in the latter. There are several other such vertical veins in the district, filled with kaolin or a little calcite and earthy matter, but none besides these two seems to have been mineralized. In the Missionary tunnel, the compact quartz matrix is from five to seven feet wide, passing insensibly into andesite, from which through alteration it has been produced. Its metallic minerals are pyrite and enargite, with more or less gold and silver, the latter being associated only with enargite. As far as known to the writer, there is no evidence of silicification or deposition of ore along the contact of the granular rhyolite with the underlying andesite.

He considers that these two characters of deposits, the contact quartz bands and the vertical veins, have a common origin and are of contemporaneous mineralization; that the absence of quartz granules in the feldspar cavities and of pseudomorphous minerals in the vertical veins may be accounted for by the difference in the character of the micro-crystalline andesite in which they occur. The vertical veins as a rule are found traversing the anticlines, but do not occur in the synclines.

With regard to the folding of the rocks, the evidence shows that, while in the earliest stages it may have advanced gradually, it culminated with considerable violence. In some cases, on the south side of the mountain, for instance, the rocks are shattered with such violence as to pile the whole mass into a promiscuous heap. It is not at all likely that these resulted from an earthquake movement subsequent to the folding, as the shattered rock is confined to the area embracing the undulations. It is impossible to conceive that mineral waters could be confined to the contact plane in the present position of the rocks; and the conclusion is therefore forcibly arrived at that the folding must have followed the silicification and ore deposition. The perfection with which the form of the Carlsbad twins is retained both by the quartz pseudomorphs and the numerous cavities present in the quartz is opposed to the notion that the mass has undergone any considerable contraction since the removal of the bases, although it is evident that more silica is contained in a given bulk of the ground-mass than was originally present in the same bulk of rhyolite base; and at the same time, it does not seem reasonable to suppose that more than a very limited amount was derived by precipitation from the altering solution. The minuteness of the crystals and the evidence of crystalline structure in the mass of the quartz, with other facts, suggest that their formation is due rather to a rearrangement of the molecules since the silicification. It is, therefore, fair to conclude that much of the silica contained in the sanidine crystals has, in a mechanical sense, taken the place of the bases in the ground-mass; in other words, that silicification has been brought about mainly by removal of the bases only.

Mr. Hills's remarks on the chemical reactions involved in the alteration and mineral deposition are too extended to be given at length. One of his main points is, that these altering solutions must have contained a certain amount of free sulphuric acid, for the reason that the bases, especially of alumina, have been removed, while silica has been left.

Silica is soluble to a limited extent in solutions of alkaline carbonates, which, however, do not affect silicate of alumina. Silica, on the other hand, is practically insoluble in solutions of alkaline sulphides and chlorides, and those containing hydrogen sulphide and free sulphuric acid; while in these solutions silicate of alumina is decomposed, and a soluble sulphide or chloride of alumina formed. Sulphuric acid may have been generated through the oxidation of hydrogen sulphide, the former existence of which may be argued from the presence of native sulphur. The disappearance of mica furnishes conclusive evidence that free sulphuric acid must have existed in the silicifying solution. The experiments of G. Rose and Kobell, as quoted by Bischof, show "that while biaxial mica resists the action of the stronger acids, uniaxial mica is completely decomposed by digestion with sulphuric acid." From this it seems that, if carbonic acid determines the decomposition of biotite, potash-mica will result; but if sulphuric acid is the decomposing agent, it may be entirely removed, as is the case in the quartz masses of the Summit District. In respect to the metallic sulphides, it is obvious, from their presence in feldspar cavities, that they have been deposited there since the alteration of the rock, and possibly under somewhat different circumstances. Those which exist in the compact matrix, however, may have been precipitated during the alteration. These may have existed as sulphates associated with alkaline sulphates, or may have been precipitated from a solution of alkaline sulphides or sulphureted hydrogen. The latter seems the most plausible supposition, as the abundance and minuteness of pyrite and enargite crystals show that decomposition took place very rapidly, and the reduction of sulphates to sulphides would require the presence of organic matter in much larger proportion than is generally found in mineral springs.

The precious metals occur in such small proportions, as compared with the baser ones, that it is not likely they exercised any material influence on the chemical changes then going on. Most of the rocks in the vicinity of the Summit District are found to contain a trace of gold, which may be inclosed in pyrite, as this mineral is frequently met with, especially in andesite. It is therefore possible that gold may have been segregated from the underlying rock. The silver was probably derived from the same source as the enargite with which it is associated, namely, that from which nearly all the ores of Southern Colorado are derived, the older Tertiary eruptives.

OXIDATION AND IMPOVERISHMENT OF SURFACE ORE AND CONCENTRATION OF GOLD IN BONANZAS.

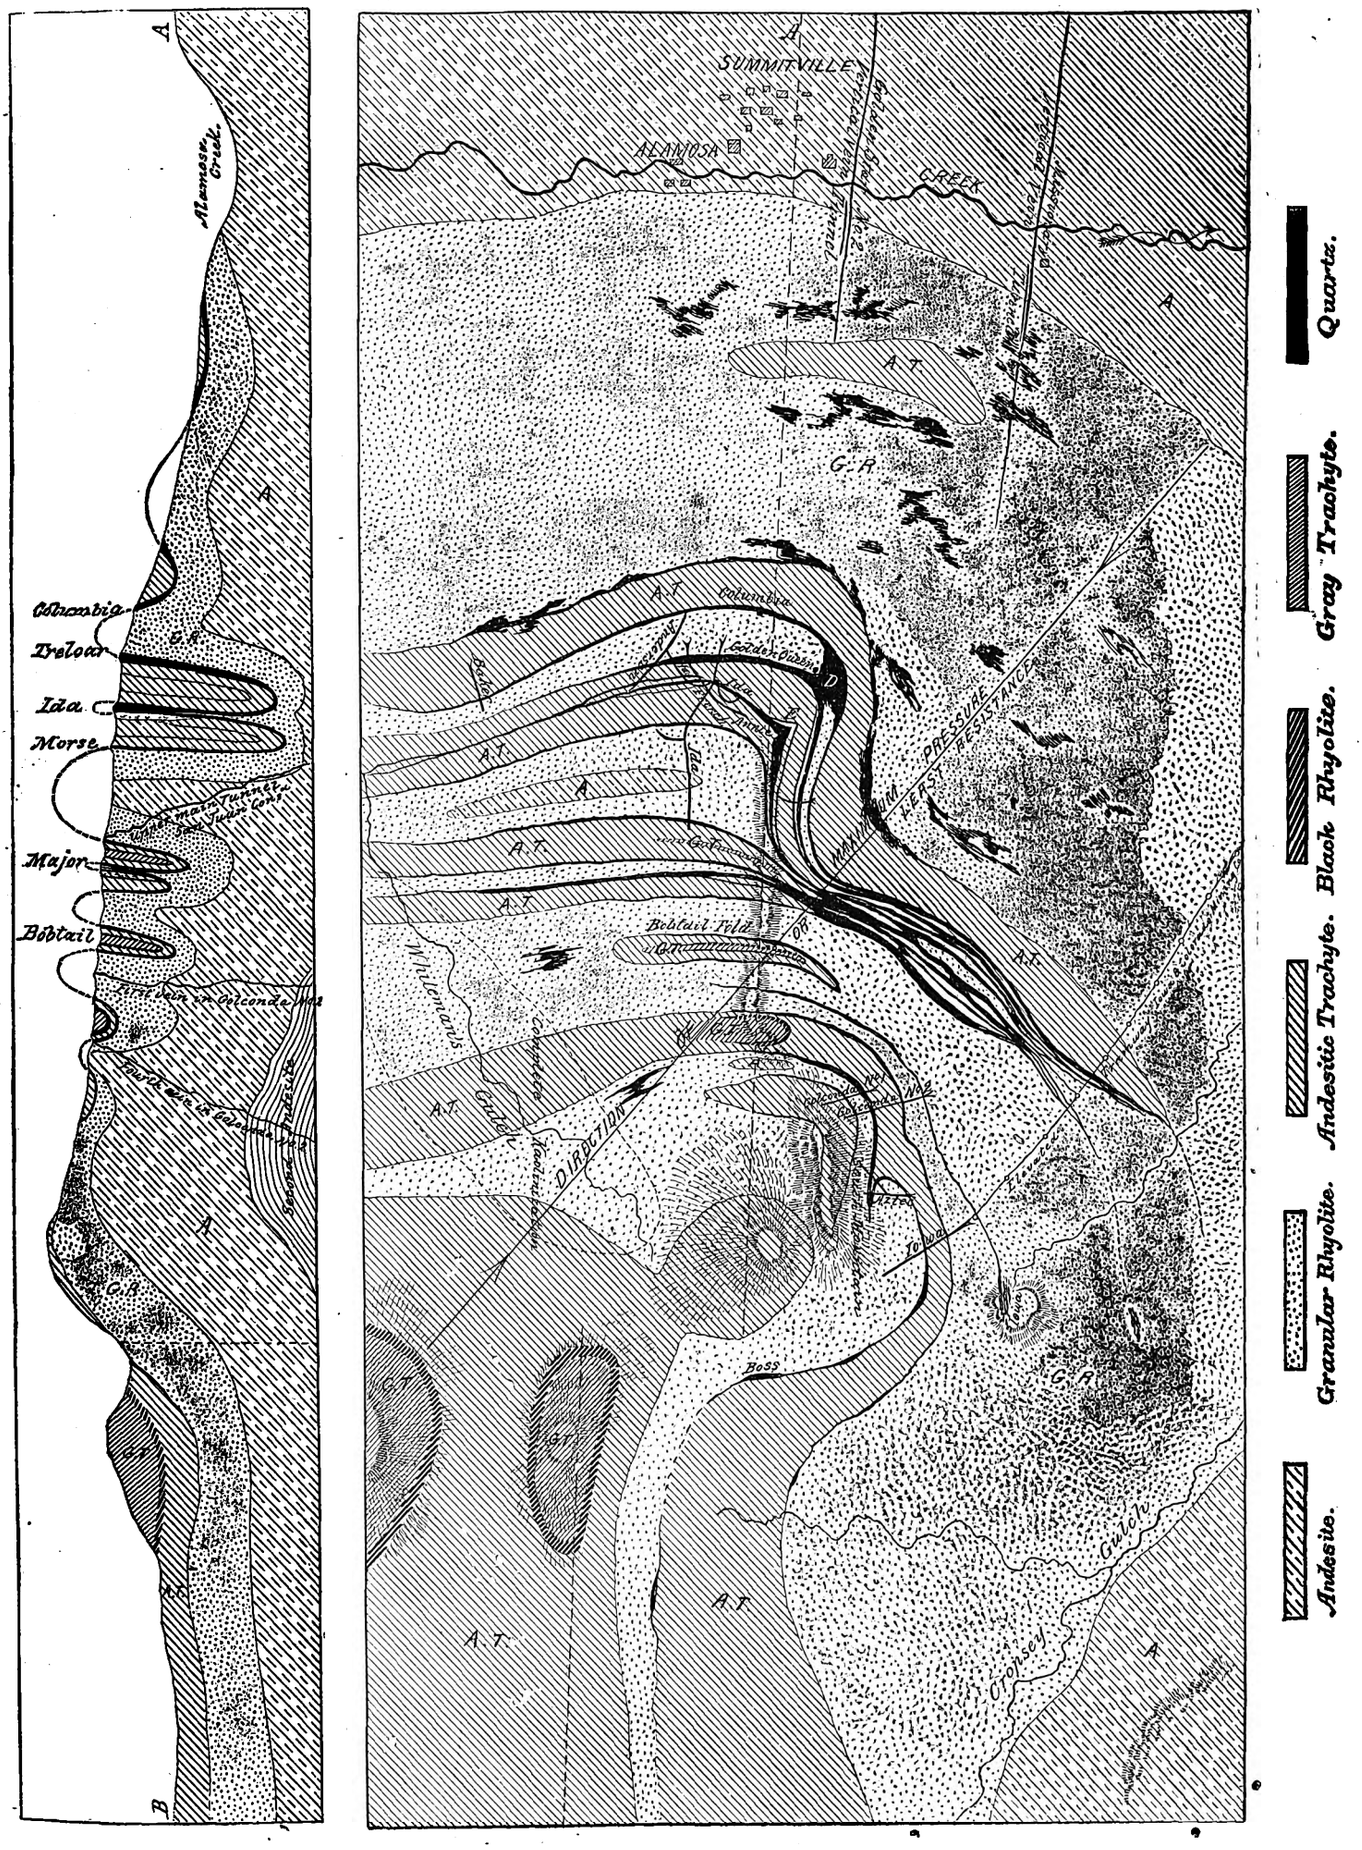
To this important subject Mr. Hills devotes considerable space, his principal result being that the gold has been concentrated by waters containing salts of iron in the central channels of the deposits, as oxidation and erosion progressed. The connection existing between gold and hydrous oxide of iron, by no means rare in gold deposits, is particularly intimate in the Summit bonanzas. In all probability, pyrite was originally disseminated through the entire mass of quartz, and sulphate of iron, and finally limonite, resulted from its oxidation. Gold is slightly soluble in ferrous sulphate, still more so in ferric sulphate, both of which salts might have been formed during oxidation of the pyrite. Limonite is very abundant along the circulating channel, near the center of the Little Annie and Little Ida bonanzas.

The concentration of silver seems to have taken place at greater depth than that of gold, and the conditions of this concentration are as yet too little known to form a satisfactory conclusion with regard to it.

Summary.—The sequence of changes which produced the existing deposits may be briefly summarized as follows:

1st. The silicification of granular rhyolite by a solution containing free sulphuric acid, and the deposition of the metallic sulphides with gold and silver.

2d. Folding of the strata or beds.



3d. The oxidation and impoverishment of the surface ore, and the concentration of the precious metals in bonanzas.

In conclusion, Mr. Hills says:

"In the preceding remarks on the genesis of these deposits, it may appear that some of the conclusions are based upon insufficient evidence; but the anomalous features presented certainly demand something more than a mere statement of observed facts. For that reason, I have ven-

Digitized by Google

tured to put forward my own views in this particular case; and although they may be only approximately correct, they are such as seem to me the most plausible under the circumstances."

Although I have not yet visited the Summit District, and can therefore give no personal confirmation of the correctness of Mr. Hills's observations, embodied in the paper of which I have made the above brief abstract, I have reason to believe that he is a correct and trustworthy observer. Moreover, his views with regard to the processes of ore-deposition, as shown therein, are in direct confirmation of those which I have held during the past few years with regard to an increasingly large class of ore-deposits. My report on Leadville shows, I think, conclusively, that ore-deposits there are the direct replacement of the dolomite rock in which they occur. While I have not yet had opportunity for studying with the same amount of detail other ore-deposits in crystalline and eruptive rocks, as shown in my chapter in the Census Report on the Precious Metals, now in press, I consider it reasonably certain that a very large proportion of the so-called fissure-veins in the Rocky Mountain region, notably those in Colorado and Montana, are simply the alteration, silicification, and mineralization of the country-rock along certain planes, which, for some reason or other, offered exceptionally easy access to percolating mineral solutions, and are not the filling-in of pre-existing cavities in the rock, as is generally supposed to be the characteristic of a true fissure-vein.

THE WORK OF THE PERNOT FURNACES AT CAMBRIA.

Mr. Magnus Troilius reports to the *Jern Kontorets Annaler* on the result of a number of runs in the Pernot furnaces at the works of the Cambria Company, at Johnstown, Pa., as follows:

Heat No. 1452; Furnace No. 2. October 22d, 1881. Side-walls, bottom, and roof had previously stood 12 heats. Time of heat, 3 hours 59 minutes. Charge: 10,000 pounds pig, 500 tons old rolls, 5000 pounds English rail crop ends, 10,000 pounds open-hearth scrap, 2000 pounds steel rail rolling-mill scrap, 6000 pounds converting mill scrap, and 500 pounds miscellaneous scrap—a total of 34,000 pounds. Furnace charged at 12.43 P.M.; charge melted, 4 o'clock; 100 pounds ore added at 4.35; 300 pounds pig added at 4.40; and 530 pounds 60 per cent ferro-manganese added at 4.43 P.M. Furnace tapped at 4.48, giving six ingots, weighing 32,450 pounds from a charge of 34,930 pounds.

Heat No. 1744; Furnace No. 2. January 4th, 1882. Side-walls and bottom had stood 7 heats and the roof 93 heats. Time of heat, 3 hours 50 minutes. The charge consisted of 7000 pounds of No. 4 pig, 3000 pounds old molds, 2000 pounds rolling-mill scrap, 15,000 pounds Scranton crop ends, 3000 pounds open-hearth scrap, and 500 pounds miscellaneous scrap—a total of 30,500 pounds. At 1 P.M., a part of the charge was in, and melting began; at 4.10 the remainder was charged, 3000 pounds being pre-heated; and at 4.20, the whole charge was melted. At 4.40, 500 pounds of No. 4 pig were added; and at 4.45, 375 pounds of 70 per cent ferro-manganese, making the total charge 31,375 pounds. At 4.50, five ingots, weighing 27,970 pounds, were tapped.

The bottom of the hearth at Cambria is made of equal parts of white sand from Mill Creek, Pa., containing 97·83 per cent of silica, 1·02 per cent of alumina, 0·88 per cent of protoxide of iron, 0·32 per cent of lime, and a trace of magnesia and of red sand from Columbia, Pa., containing 89·14 per cent of silica, 8·91 per cent, of alumina, 1·01 per cent of protoxide of iron, and 0·51 per cent of lime.

THE IRON ORES OF THE VALLEY OF VIRGINIA.*

By Andrew S. McCreath, Harrisburg, Pa.

Having recently been called upon by the Shenandoah Valley and Norfolk & Western railroad companies to make an examination of the iron ores in the Valley of Virginia tributary to their lines of railroad, it has been suggested to me that a brief statement in regard to some of the more important points might prove interesting to my fellow-members of the Institute at this meeting.

The Valley of Virginia, so-called, extends from the Potomac to the Tennessee line, a distance of about 330 miles. It forms part of the Great Limestone Valley which traverses in an unbroken line the States of New York, New Jersey, Pennsylvania, Maryland, Virginia, and Tennessee. In New York State, it is called the Wallkill Valley; in Eastern Pennsylvania, the Kittatinny Valley; in Middle Pennsylvania, the Lebanon or Cumberland Valley; in Virginia, the Shenandoah or Winchester Valley, the Roanoke Valley, the James River Valley, and the New River Valley; and farther south, the Valley of East Tennessee.

Two ranges of mountains hem the valley in. The range on the southeast is called the South Mountains in Pennsylvania; the Blue Ridge, with its southwest prolongations, Poplar Camp and Iron Mountain, in Virginia; and the Smoky Mountains in Tennessee. The range on the northwest is usually called the North Mountain; but it has such local names as Shawangunk, Kittatinny, Blue and Brushy Mountain.

The primary rocks consisting of granitic strata (gneiss) and crystalline slates (mica slate, chlorite slate, etc.) form the Eastern Blue Ridge, while the Primal or Potsdam sandstone formation lies upon its western slope along the southeast edge of the valley. The valley itself varies in width from ten to twenty miles, and its floor is composed of two different kinds of rock, limestone and slate, separated from each other by an irregular line running along the middle of the valley its whole length, the limestone land stretching to the foot of the South Mountain, and the slate land stretching to the foot and up the slope of the North Mountain. The North Mountain consists of Upper Silurian rocks—Oneida conglomerate and Medina sandstone, Formation No. IV.; except in Southern Virginia, where, by reason of the great upthrow faults, the Vespertine or Pocono sandstone, Formation No. X., makes the North or Brushy Mountain. It will be sufficient, however, for my present purpose, to consider only the two great geological formations: No. I., the Primal or Potsdam sandstone formation; and No. II., the Lower Silurian limestone formation; for it is in these that nearly all of the ores which I have examined occur.

Formation No. I.—The Primal or Potsdam sandstone formation consists of conglomerates, sandstones and slates, and it may be conveniently divided into (1) lower slates, (2) sandstones, and (3) upper slates.

First. In the *lower slates*, or those geologically underneath the Potsdam sandstone, occurs a red hematite ore, sometimes in beds of considerable thickness and of good quality. This is the so-called "specular ore" of the Blue Ridge, and it has been quite extensively developed at numerous points, notably in Botetourt and Bedford counties. In Northern Virginia, the ore is generally very lean, being little better than a ferruginous sandstone. But over large areas it is a fairly rich ore carrying from 40 to 45 per cent metallic iron, with the phosphorus varying from 0·25 to 0·60 per cent. The siliceous matter varies from 25 to 35 per cent, and consists for the most part of small grains of quartz. The ore occurs in beds varying from 18 to 40 inches in thickness, although beds of much greater thickness have been reported. The following is a complete analysis of a sample of this ore from the "Pollard cut" on the Arcadia furnace property, in Botetourt County:

Protoxide of iron	1·221	Sulphuric acid	·007
Sesquioxide of iron	55·928	Phosphoric acid	·607
Sesquioxide of manganese	·043	Water	3·144
Alumina	1·808	Siliceous matter	35·690
Lime	·730		
Magnesia	·706		99·884
Metallic iron	40·100	Phosphorus	·265
Metallic manganese	·030	Phosphorus in 100 parts iron	·660
Sulphur	·003		

Second. In the *Potsdam sandstone* itself, important beds of iron ore have been observed. The ore is generally a close-grained, brittle, dark-brown hematite, invariably cold-short. In Rockbridge County, a bed of it fully ten feet thick is exposed for a considerable distance on the Vesuvius property. The ores from this horizon will probably average 50 per cent metallic iron, with about one and a quarter per cent phosphorus. Their composition is such that they are peculiarly adapted to the manufacture of pig-iron for conversion into steel by the basic process; as it has been found that a pig-iron with about two and one half per cent phosphorus gives the most satisfactory results. The following complete analysis of a sample from the "cold-short" bank on the Vesuvius property, Rockbridge County, will show the ultimate composition of the ores of this horizon:

Sesquioxide of iron	74·893	Sulphuric acid	·012
Sesquioxide of manganese	·433	Phosphoric acid	3·357
Sesquioxide of cobalt	·030	Water	11·318
Oxide of zinc	None.	Siliceous matter	8·050
Alumina	1·005		
Lime	·740		100·198
Magnesia	·360		
Metallic iron	52·425	Phosphorus	1·466
Metallic manganese	·302	Phosphorus in 100 parts iron	2·796
Sulphur	·005		

Third. The *upper slates*, however, are by far the most important from an economical stand-point, forming, as they do, one of the richest repositories of brown hematite iron ore in Virginia. They intervene between the Potsdam sandstone and the base of the Calciferous limestone, and they are found all along the western slope of the Blue Ridge, being geologically coextensive with it. They are generally more or less disintegrated or decomposed into variegated clays; and while they may not always carry a continuous ore-bed, yet wherever the formation exists, deposits of iron ore of greater or less extent may be confidently looked for. It is this horizon which has supplied a large amount of iron ore to the blast-furnaces of Pennsylvania, and it has been the source of practically the whole of the stock of the old charcoal furnaces of the Shenandoah Valley: to the Shenandoah Iron Company's furnaces, from the noted Smith and Fox Mountain ore-banks in Page and Rockingham counties; the old Mount Torry furnace in Augusta; Cotopaxi, Buena Vista, Vesuvius, and Glenwood furnaces in Rockbridge, and the Arcadia and Cloverdale furnaces in Botetourt County. The new modern coke-furnace recently established at Roanoke by the Crozer Steel and Iron Company will also be largely supplied with ores found in this formation at the company's mines in the so-called Cloverdale ore-belt.

It would be tedious to mention all the localities where large deposits have been developed and are now successfully worked; and the increased railroad facilities afforded by the completion of the Shenandoah Valley Railroad will doubtless be the means of greatly stimulating their further development by more thorough and systematic methods of mining.

The average character of the ore is good, and in some localities it is exceptionally fine. The average of 31 carefully selected samples shows the following: Metallic iron, 49·956; phosphorus, 0·399; siliceous matter, 12·459. The iron varies from 38·95 to 56·55 per cent, and the phosphorus from ·061 to 1·266 per cent. Eighteen of the samples show considerably over 50 per cent metallic iron, and only one sample shows less than 40 per cent.

The following complete analyses will represent the character of some of the more important deposits. The samples represent the *lump ore* alone; and the ores were dried at 212° Fahr. previous to analysis:

	No. 1.	No. 2.	No. 3.	No. 4.
Sesquioxide of iron	74·678	75·321	77·643	74·571
Sesquioxide of manganese	4·619	1·831	·568	2·038
Sesquioxide of cobalt	·080	·130	·020	None.
Oxide of zinc	·040	·050	Trace.	None.
Alumina	1·415	2·100	·747	·951
Baryta	None.	None.	None.	·040
Lime	·670	·550	·430	·550
Magnesia	·320	·331	·324	·356
Sulphuric acid	·052	·025	·040	·040
Phosphoric acid	·233	·609	·446	·444
Water	11·810	12·398	10·310	10·822
Siliceous matter	6·310	6·910	9·390	10·450
	100·227	100·255	99·918	100·269
Metallic iron	52·275	52·725	54·350	52·200
Metallic manganese	3·216	1·275	·396	1·419
Sulphur	·021	·010	·016	·016
Phosphorus	·102	·266	·195	·194
Phosphorus in 100 parts iron	·195	·504	·358	·371

vey of Pennsylvania to sample and analyze every important deposit of brown hematite ore that has been opened up along the flank of the South Mountains in Pennsylvania, which is simply a continuation northward of this same ore-belt. The average of 46 samples from the Cumberland Valley shows: Metallic iron, 42·95; phosphorus, ·464 per cent; and it is believed that the brown hematite ores at present mined in the Lehigh Valley will not average over 40 per cent metallic iron in the furnace. It will thus be seen that the ores from this horizon in the Valley of Virginia rank considerably above the average.

In these upper slates are also found important deposits of manganiferous iron ores, some of which might be used in the manufacture of spiegel. The average of six samples analyzed shows: Metallic iron, 31·64; metallic manganese, 19·12, equal to 50·76 total metallic contents; with the phosphorus averaging ·130 per cent. The variations are as follows: Iron, from 12·325 to 47·15; manganese, from 7·277 to 44·312; and phosphorus, from ·061 to ·265 per cent, with the average as stated above.

In addition to these, rich deposits of a very pure manganese ore have been successfully worked for a number of years. Thus far, the most important is that at the Grimora mines in Augusta County; and the deposit seems so large, and the ore is of such fine quality, that I give in detail the analysis of an average sample of the *lump ore*, now quite extensively shipped to England:

Binoxide of manganese	81·703	Lime	·880
Protoxide of manganese	7·281	Magnesia	·630
Sesquioxide of iron	·533	Sulphuric acid	None.
Oxide of cobalt	·354	Phosphoric acid	·171
Oxide of nickel	·096	Alkalies	·467
Oxide of zinc	·623	Water	3·405
Oxide of copper	None.	Silica	2·132
Alumina	·896		100·000
Baryta	·829		
Metallic manganese	57·291	Phosphorus	·075
Metallic iron	·373		

Formation No. II.—In the body of the Great Limestone Formation, No. II., are found innumerable caverns and pot-holes, now filled with brown hematite iron ore. Although such deposits may prove somewhat irregular, yet their extent is often very great, and they have yielded large quantities of the finest quality of ore. In the northern part of the Valley of Virginia, these limestone ores have not been developed to any great extent; but in Southwest Virginia, they have furnished practically the whole of the stock to the charcoal furnaces of the district. Commencing at Mack's Creek near New River, and pursuing a course parallel to Poplar Creek and Iron Mountains for a distance of thirty or forty miles, they have been developed in large quantity and of remarkable purity. This is generally known as the New River-Cripple Creek Ore-Belt; and the cold-blast charcoal furnaces of Wythe County, whose iron is in good repute for car-wheel purposes, draw their supply of ore exclusively from this belt.

The ore occurs generally mixed with clay in clefts and cavities in the limestones; and some of the deposits have been proved to a depth of over one hundred feet. The bulk of the ore is wash-ore, and the wash material will average fully one half clean ore. At some points, however, the workings show quite a good deal of lump ore; and this not infrequently carries an appreciable amount of iron pyrites, which occurrence may be suggestive of the origin of the ore. The superior quality of the ore is shown by the analyses of seventeen samples from different localities, yielding an average of: Metallic iron, 54·514; phosphorus, 0·106; siliceous matter, 7·094 per cent. The iron varies from 49·35 to 57·20; the phosphorus from ·048 to ·197; and the siliceous matter from 3·60 to 13·93. Nine of the samples show over 55 per cent metallic iron, and only one contains less than 50 per cent; and in no case is the phosphorus over ·200. The general character of these limestone ores may be represented by the following complete analyses:

	No. 1.	No. 2.	No. 3.
Bisulphide of iron	None.	·064	None.
Protoxide of iron	None.	·047	None.
Sesquioxide of iron	76·214	80·618	73·167
Sesquioxide of manganese	·051	·103	1·334
Oxides of nickel and cobalt	·040	·060	·110
Oxide of zinc	None.	·150	·220
Oxide of lead	None.	·184	None.
Oxide of copper	None.	Trace.	None.
Alumina	2·365	1·476	1·410
Lime	·820	·750	·710
Magnesia	·486	·515	·677
Sulphuric acid	·157	·092	·012
Phosphoric acid	·171	·110	·451
Water	12·072	11·174	10·576
Siliceous matter	7·480	4·500	11·510
	99·856	99·843	100·117
Metallic iron	53·350	56·500	51·175
Metallic manganese	·036	·072	·929
Sulphur	·063	·071	·005
Phosphorus	·075	·048	·197
Phosphorus in 100 parts iron	·140	·085	·384

No. 1. Rich Hill, or Forney property, near New River. No. 2. New River Mineral Company's property (Van Liew's). No. 3. Speedwell Furnace property.

In addition to the ores already mentioned, I desire to call attention to another remarkable group of ores occurring in the Great Limestone Formation, and found at several points in Southwest Virginia and Eastern Tennessee, namely, red hematite and magnetic iron ores. These may be said to be as yet practically undeveloped; for the ores were found to be too refractory for the small cold-blast charcoal furnaces of the district, and the lack of railroad facilities prevented their finding an outside market.

Sometimes the ore is a dense, fine-grained red hematite, with a steel-blue color on fresh fracture, as at the Sharp, Thomas, and Crockett banks in Sullivan County, Tennessee; again, it is a fine, rich magnetic ore, as shown at the Ripplemead mine on New River, near Pearisburg, Giles County, Va., from which about 5000 tons have recently been mined and shipped to Harrisburg, Pittsburg, and other points. Sometimes the ore changes into brown hematite; and indeed, all three varieties may occasionally be found in the same opening. But whether the ore be red or brown hematite, or magnetite, it seems to possess the uniform feature of being very free from phosphorus. An exception might perhaps be sometimes made to the magnetite. At some points, this has been found to be more or less impregnated with slaty material, and when this is the case, the phosphorus may run somewhat higher; for I have observed that quite an appreciable amount of phosphorus is sometimes carried in the slate. But when the ore is free from this slaty gangue, the percentage of phosphorus is invariably low; and even where the ore carries considerable slate, the phosphorus has never been found over one tenth of one per cent. It may prove interesting to note here that the magnetite is generally strongly impregnated with carbonaceous matter, sometimes to the extent of two or three per cent.

At the Sharp and Thomas banks, in Sullivan County, Tennessee, the ore (red hematite) is reported from 5 to 10 feet thick, between walls of limestone; but owing to the difficulty of reducing these hard, dense ores in the small local furnaces, the openings have long been abandoned. Increased railroad facilities and the present demand for high-grade ores will doubtless be the means of having these deposits receive the attention which the fine quality of their ore seems to justify. The analyses of nine samples of the red hematite and magnetic ores yield the following average: Metallic iron, 62·094; phosphorus, ·032; siliceous matter, 5·290. The iron varies from 56·05 to 66·47; the phosphorus, from ·020 to ·051; and the siliceous matter, from 2·89 to 7·90. Separate analyses of four samples of the accompanying brown hematite show an average of: Metallic iron, 54·532; and phosphorus, ·031.

The following complete analyses will show the general character of these ores:

	No. 1.	No. 2.
Protoxide of iron	12·117	1·928
Sesquioxide of iron	66·607	90·214
Sesquioxide of manganese	None.	None.
Alumina	2·197	1·863
Lime	1·890	·500
Magnesia	1·982	·317
Sulphuric acid	·150	·020
Phosphoric acid	·082	·050
Carbonic acid	1·806	None.
Water and carbonaceous matter	5·458	1·834
Siliceous matter	7·760	2·975
	100·049	99·701
Metallic iron	56·050	64·650
Metallic manganese	None.	None.
Sulphur	·060	·008
Phosphorus	·036	·022
Phosphorus in 100 parts iron	·064	·034

No. 1. Golleher bank, Washington County, Virginia. Magnetic iron ore. No. 2. Crockett bank, Sullivan County, Tennessee. Red hematite.

In view of the fact that the iron ores of the Valley of Virginia are of such superior quality, and there is sufficient evidence that they exist in large quantity, it may well be asked, Why have they not been more largely developed? Two reasons may be given, and these are: 1. Previous lack of railroad facilities; and 2, an insufficient supply of fuel for reducing the ores in the blast-furnace. Although ever since early colonial times, numerous small charcoal furnaces have been operated from time to time, producing a fine quality of pig metal, yet the lack of facilities for getting their product to market, and the gradual diminution of their fuel supply, together with the ravages caused by the late war, have not only greatly retarded their extension, but have prevented the establishment of other enterprises. These obstacles, however, have now been overcome by the completion of the Shenandoah Valley Railroad from Hagerstown to Roanoke, thus affording ample railroad facilities; and by the building of the New River division of the Norfolk & Western Railroad to open up the great Flat Top coal region, with its superior coking coals. The New River-Cripple Creek ore-belt will soon be supplied with convenient railroad communication; for a branch road has already been located, and there are good prospects that the line will be built in the near future.

During the present year, the two pioneer *coke* furnaces of the valley have been started, and are now in successful operation. The Shenandoah Iron Company's furnace at Milnes Station on the Shenandoah Valley Railroad was blown in during the month of February, and it has been producing from 60 to 70 tons of coke iron per day ever since. The Crozer Steel and Iron Company's furnace at Roanoke has just been started, and it promises a successful future; for it has all the modern and improved appliances, combined with an intelligent management. Both of these furnaces will draw their supply of coke (made from Flat Top coal) from the ovens of the Southwest Virginia Improvement Company at Pocahontas. This company commenced operations in February, 1882, by opening up the Nelson or Big bed of coal. It is now building 200 beehive coke-ovens, and it expects to have a daily production of at least 250 tons of 48-hour coke, which output can readily be increased to meet future demands. In addition to this, it will ship a thousand tons of coal daily. Already in its preparations for regular mining, it has taken out from the various drifts some 40,000 tons of coal. The main drifts are 9 feet wide and 8½ feet high, and the mine will be worked by the double-entry system of mining. The quality of the coal is very fine, as shown by the following analysis of samples selected from five different points in the drifts—the samples representing a complete section of the coal-bed from roof to floor.

Water	·932	Sulphur	·618
Volatile matter	20·738	Ash	3·984
Fixed carbon	73·728		100·000
Phosphorus			·0013

This brief statement will suffice to show, in a general way, the mineral resources of the valley. With a convenient supply of the finest quality of coke, which the Flat Top coal promises to furnish; with a great variety and abundance of excellent iron ore, which can be cheaply mined; and with good railroad facilities to markets in every direction, the iron interests of the Valley of Virginia seem assured of a prosperous future.

MR. W. W. HABIRSHAW, chemist, of this city, reports the following as the analysis of the steel made in the Henderson furnace, referred to in a recent issue: Carbon, 0·0014 per cent, and phosphorus 0·1528 per cent. It will be noted that the carbon is exceptionally low, 0·2 having been aimed at, a proof of the unexpectedly great oxidizing character of the flame.

THE SPELTER PRODUCTION OF EUROPE.

In our last issue, we printed an estimate of the spelter production of Europe for 1881, by an Austrian statistician. The following is a statement for 1882, compiled by Herr Landsberg of the Stolberg Works, Germany:

	1882.
Rhenish Provinces and Westphalia	45,354 metric tons.
Silesia	69,846 "
Belgium and France	91,800 "
Spain	4,500 "
England	25,000 "
Austria	4,000 "
Poland	4,500 "
Total	245,000 "

These figures are evidently erroneous in some points. Belgium and France together are probably nearer 100,000 tons, and Spain produces now at the rate of fully 7000 tons per annum, while the English figure looks excessively high.

THE LEAD PRODUCTION OF GERMANY IN 1882.

Herr Landsberg, the able manager of the Stolberg Works, has published the following detailed production of the German lead works:

	Lead. Metric tons.		Silver. Kilograms.	
Prussia:	1882.	1881.	1882.	1881.
Stolberg Company	14,919	13,996	26,130	20,227
Rheinisch Nassau Company	6,239	7,200	7,608	6,212
Mechernich Company	25,055	22,409	5,108	4,438
Commern Company	2,727	2,362	988	1,181
A. Poensgen & Söhne	3,100	3,189	1,175	1,382
Rothenbach Works	40	55	901	969
Walther Cronek Works	5,858	5,489	3,679	4,056
Friedrichs Works	8,683	8,450	5,245	5,532
Mansfeld Works	.....	.....	62,708	59,836
Hanover:				
Upper Hartz	10,447	9,428	32,592	26,385
Lower Hartz	579	424	3,375	3,854
Nassau:				
Ems	5,803	5,772	7,403	6,887
Braubach	3,176	2,721	6,085	5,515
Saxony:				
Freiberg	5,064	4,494	50,985	39,133
Total	91,690	85,989	213,982	185,607

In addition to this, the German works produced 4170 tons of litharge in 1882, against 4227 tons in 1881.

A NEW NOTE-BOOK.—Messrs. Keuffel & Esser, of this city, have published a new Transit Book for the Use of Engineer on Railroad Surveys. Its novelty consists in having printed on the last three leaves all the tables and curve formulæ necessary for the location of a railroad. By the use of these note-books, the necessity for carrying an engineer's field-book of tables is avoided. The cost is not materially increased, and they will be found very convenient.

EXPERIMENTS made in the Saarbrücken coal district with the lime process seem to indicate that the action of slacking compressed caustic lime with water is chiefly by means of the expansion of the lime cartridge. The breaking down of the coal seems to depend very little upon the generation of steam of high pressure. The ordinary explosive test in lead cylinders showed that the lime has only to a limited degree the attributes of an explosive.

SILVER PRODUCTION OF BOLIVIA.—A Lima letter in the New York *Herald* gives Bolivian statistics which are very difficult of access. If they be correct, they are doubly acceptable. They are certainly new, although they cover the year 1881 only, when the exports from Bolivia are said to have been as follows:

Silver from Oruro, Potosi, and Chinchas, 71,101 kilos	$3,086,000
" " Huanchaca and Guadalupe, 85,935 kilos	5,811,130
Copper from Corocoro, 3,250,600 kilos	420,000
Tin	458,000
Argentiferous lead	6,268
Bismuth	61,819

ELECTROLYTIC EXPERIMENTS.—In the *Journal* of the Chemical Society for May is an abstract of a paper by A. Bartoli and G. Papasogli, on the results of the electrolysis of various solutions. From the experiments they have made, the authors draw the following general conclusions: 1. In liquids whose electrolysis is not accompanied by evolution of oxygen at the anode, wood charcoal, retort-carbon, and graphite are not disintegrated, and do not suffer any appreciable loss of weight. 2. On the contrary, in liquids whose electrolysis gives rise to liberation of oxygen at the anode, wood charcoal, retort-carbon, and graphite, employed as positive electrodes, are partly disintegrated and partly oxidized to carbonic oxide and carbonic acid (the relative quantities of which depend upon the strength of the current and the superficial area of the positive carbon), together with other products varying according to the nature of the carbon. 3. Graphite used as positive electrode in these liquids never colors the electrolyte, whereas retort-carbon and charcoal previously purified by the action of chlorine at a high temperature color the liquid deep black, both in alkaline solutions and in those of certain acids and their salts. 4. Charcoal or retort-carbon employed as positive electrode in solutions of acids or of neutral salts whose electrolysis gives rise to evolution of oxygen at that electrode forms chiefly, or rather almost entirely (beside carbonic oxide and carbonic acid), a black substance—called by the authors mellogen—whose composition is represented by the formula $C_{14}H_8O$, or a multiple thereof, together with mere traces of benzo-carboxylic acids; while in solutions of phosphoric acid, hydrofluoric and potassium antimonate, a substance is formed analogous to mellogen in its properties, but containing phosphorus, fluorine, or antimony, according to the electrolyte employed.

FURNACE, MILL, AND FACTORY.

Ex-Commander Gorringe, in the ships he is building at Philadelphia, is going to use the Bower-Barff process for protecting those parts of iron and steel which are inaccessible after the ship is completed.

A. Garrison & Co., of Pittsburg, have just sent a train of three-high plate rolls 31 by 112 inches to the Springfield iron mill. They are building rolls for the Maumee Rolling-Mill Company, Toledo, Ohio.

The Spang Steel and Iron Company, of Pittsburg, is rolling its universal mill steel plates 40 feet long and somewhat under 8 feet wide. It can roll plates 9 feet wide. It is also rolling a large quantity of angle steel, to be used in building the new bridge intended to span the Niagara River.

The Springfield Malleable Iron Company, of Springfield, Ohio, is increasing the capacity of its works fully 50 per cent. It is putting in one additional air-furnace, three annealing-ovens, and a molding-room 100 by 75 feet, which will give it a capacity of 3500 tons of iron a year. These improvements will be finished about June 15th, and then the company will employ 250 men.

The Bullard Repeating Arms Company intends to erect, either in Springfield or Worcester, Mass., a building 168 by 40 feet, and four stories high, with a tower at one end. This building will give facilities for working 200 men, the company having orders enough to employ that number, and leave a space for a 120-foot addition on the other side of the tower when the business shall require it. Nothing is settled yet as to location. Springfield capitalists are working hard to secure it. The company expects to have its buildings erected and ready for occupancy in September.

An Associated Press dispatch reports: The Grafton Iron Company, of Leetonia, Ohio, has failed. Its liabilities are about $600,000. Two large concerns in Pittsburg—Graff, Bennett & Co., iron manufacturers and furnace-men, and Robinson Rea—are stockholders in the Leetonia corporation. Their solvency is undoubted. All rumors to the contrary disregard the fact that their own indebtedness would have to be paid before any claims on the score of the Grafton Company could come upon them. Both firms are extensive, and have always been managed with the most conservative views. The Elba Iron-Works have also been mentioned as being in trouble, but a correspondent of the Associated Press is informed by an undoubted authority that there is no foundation for the report.

The wheels of a new locomotive which have just been built at Salt Lake City were cast from pig-iron made at the Ogden Iron-Works, and hence are strictly a Utah production. The frame-work of the engine was forged in those shops, and the locomotive represents Utah labor and skill, and partly Utah material.

The reverberatory gas-furnace, already successful in smelting iron and steel, has now, according to the *American Manufacturer*, proved equally so in the treatment of fine ores. An old style furnace in the plant of the Miners' Smelting and Reduction-Works at Golden, Colo., was recently remodeled into a McNair gas-furnace. Slack is used as effectively in it as lump coal. Pittsburgers are largely interested in this experiment, as among the stockholders in the Miners' Smelting and Reduction-Works at Golden are Messrs. R. B. Townsend, the secretary and treasurer; W. W. Young, E. T. Dravo, Matthew Graff, John Graff, Thomas J. Graff, B. L. H. Dabbs, and W. B. Neale.

The Missouri Malleable Iron Company, of St. Louis, has decided to increase its capital stock from $50,000 to $100,000. It will also gradually increase the capacity of its already extensive works.

E. G. Denniston, proprietor of the San Francisco Plating-Works, has achieved a notable feat in his line, in the manufacture of the largest silver-plated amalgamating plates, for saving gold, ever made. These plates are five by eight feet—each containing forty square feet of amalgamating surface. These plates have been shipped to Denver, Colorado, where they are to be used for amalgamating purposes. They are made of the best Lake Superior copper heavily plated on one side with pure silver, and are ready for instantaneous amalgamation by the application of quicksilver to the plated surface. The dynamo machine has a capacity of depositing fifty-five ounces of silver per hour. It is from the Mather Dynamo-Electrical Manufacturing Company, of Hartford, Conn. Mr. Denniston claims to have, at his works, the largest tank for electro-plating purposes in the United States, if not in the world. Extensive additions and improvements are making in his works.

Judge Treat, in the United States Circuit Court, at St. Louis, has recently rendered a decision of great importance to nearly every part of the United States, settling the great barbed wire fence controversy. The court holds that the patents issued to Kelly & Glidden are void, and therefore refused to grant the preliminary injunction asked for by the Washburn & Moen Manufacturing Company and Isaac L. Ellwood. The Washburn Company likewise sought an injunction against Gustave Griesche and Henry Fuchs relative to the manufacture of patent machines for barbed wire. This injunction was refused, on the ground that there was no infringement. The earliest barbed wire patent was issued in 1867 to one Hunt, since which time the issues and reissues have been almost innumerable. All of these, or at least all of them that possessed practical business features, have been from time to time acquired by the Washburn & Moen Manufacturing Company of Worcester, Mass., and Isaac L. Elwood of De Kalb, Ill., the plaintiffs in the cases referred to. Of all the numerous patents the only practical ones are those known as the Kelly & Glidden patents, the original issue of which has been claimed by the defendants in the suits, enlarged and amplified out of all knowledge by subsequent reissues. It is precisely here that the controversy took place and where the battle has been fought out. If the reissues had been declared to be within the meaning and intention of the original patents, or if they are, in other words, valid, the defendants would have been guilty of infringement. If otherwise, and the courts declared the reissues vitally at variance with the original patents and invalid, the business of manufacturing barbed wire would be thrown open without restriction.

GENERAL MINING NEWS.

ARIZONA.

Glowing reports coming from Turkey Creek state that important strikes have been made there. The whole country for a mile and a half on each side of the original discovery is monumented, and the excitement runs high. A new town-site has been located and incorporated, and in all probability a new town will come into existence within the next sixty days. The country for miles in every direction is permeated with ledges of high-grade ore.

COPPER MOUNTAIN.—This company's smelter, during the thirty-hour trial run, produced six tons of black copper, which were run into bars of from 600 to 700 pounds each. The mines consist of the Copper Mountain and the first south extension of Copper Mountain. Both of these claims are constantly worked. Thirty-two hundred tons of ore are on the dump, consisting mostly of carbonates, red and black oxides, and some black and gray copper.

TOMBSTONE DISTRICT.

TOMBSTONE MILL AND MINING COMPANY.—The superintendent telegraphs as follows: Gross output for May: Mill, $53,600; furnace, $23,000 for twenty-one days. Furnace runs without any trouble and works forty tons daily. The

mine looks well. We have begun fourth level, west side; new ore-body in Tough Nut yielding well.

CALIFORNIA.

MONO COUNTY—BODIE DISTRICT.

BODIE CONSOLIDATED.—The official report for the week ended May 26th shows: Ore crushed, 172·08 tons; average assay value of pulp, $45.45 per ton; of tailings, $6.50 per ton. Bullion shipped, $5182.02. West cross-cut, 1000 level, is in 240 feet. North drift, same level, is in 160 feet. North drift, 800 level, is 490 feet long. Winze No. 5 is 28 feet deep; the rock continues hard and the vein narrow. From near the end of the north drift from winze No. 5, 672 level, a rise was started last week; rise now up 10 feet. It will be known as rise No. 23, and will probably open up a block of fine ore to the 640 level and north of winze No. 6. South drift from winze No. 5 is 166 feet long, and shows some good ore in the face.

BODIE TUNNEL.—The ore formation is again looking favorable in all the workings of the mine. Lately 16 feet were added to the length of the west cross-cut from the 300-foot level. The north drift on ledge No. 21 has been advanced 7 feet. The north drift on the east ledge has been advanced 12 feet in ore 3 feet in width. The south drift on ledge 21, 300-foot level, has been advanced 3 feet. The ore is 2½ feet wide. The mill is crushing about 40 tons a day.

GREENVILLE DISTRICT.

PLUMAS CONSOLIDATED.—A vein of ore about four feet wide has been struck in a prospect-tunnel. The ore is of fair quality, the ledge appears to be well defined, and stands nearly vertical. It is thought that this vein is only a stringer, and will soon run into a much larger ore-body.

WILES.—The parties interested in this ledge, which shows favorable prospects, intend to lease the Kettle mill and proceed at once to work the mine. The distance from the mine to the mill is only a few hundred yards. The ore can be got and worked very cheaply.

CANADA.

PROVINCE OF NOVA SCOTIA.

GALLIHAR GOLD MINING COMPANY.—It is stated that the company is so much encouraged by the results of the operations at its mine at Isaac's Harbor, Guysborough County, that it proposes extending its works.

ONTARIO.

WALLBRIDGE.—Pumping machinery has been erected at this mine and work will be commenced shortly.

WINNIPEG.

The Argyle has struck rock that will go $69 to the ton.

The depth attained by the Winnipeg Consolidated is ninety-five feet, with four drifts.

William Young left last Wednesday for the property of the International Company, which he is stripping and making ready for its inspection.

Mr. John T. Nagle, superintendent of the George Heenan Company, states that they are sinking on the vein, and that he considers the indications particularly favorable.

A location was surveyed lately by Messrs. Davidson & Smith, for Messrs. Simpson, Newell, and others of Keewatin. The vein is situated near that village, and, judging from specimens shown, is rich in the precious metal.

A portable stamp-mill was shipped on Saturday for Clearwater Bay by Messrs. Thomas & Co., for the purpose of working a location at that point, the property of the Mining Investment Company.

COLORADO.

CHAFFEE COUNTY.

CHAFFEE CITY.—The name of this town has been changed to "Monarch" by the Postmaster-General, to take effect after July 1st next. This was done in accordance with a petition numerously signed by the citizens. Indications point to active work in the mines of this locality this season, and good reports may be expected.

CLEAR CREEK COUNTY.

We glean the following from the Georgetown *Miner*:

BONANZA TUNNEL.—This enterprise is now in nearly 600 feet on the west side of Democrat Mountain. At a distance in of 330 feet, it cuts the Jordan lode about 120 feet deep. A drift has been run about 220 feet east on the Jordan, which produced, with some stoping, about $3000. A streak has been struck from three to ten inches thick of solid galena ore, carrying considerable gray copper and running about 500 ounces silver per ton. Eighty-five feet beyond the Jordan, a blind lode was struck, from two to three feet wide, with streaks of mineral through it, the average assays from which were 150 ounces. From this lode, the tunnel has been run 175 feet in barren ground.

DUMONT.—In the Lincoln tunnel, which is about 600 feet in, they struck the California lode at a depth of about 300 feet, which shows a foot of solid gray and yellow copper.

LITTLE EMMA.—The Matthews tunnel connected with the main shaft about April 1st, at a depth of 440 feet below the present working tunnel level, and about 640 feet below the summit of Democrat Mountain. The Matthews tunnel is 1250 feet long where it connects by an eighty-foot winze with the sixth level, which latter connects 200 feet farther east with the main shaft now down 360 feet below the working tunnel level. Seven men are working on a single-day shift, principally in the fifth level, which is now about 120 feet west of the main shaft. This will be continued eighty feet, so as to connect with the eighty-foot winze from the sixth level to the Matthews tunnel. This same connection will be made with all the levels, when rock and ore can all be shipped by gravity from 440 to 640 feet, thus saving an immense sum for hoisting. The Matthews tunnel is run all the way on the lode and cost an average of $6.50 per foot to run it.

MENDOTA.—Shipments from this mine for May were thirty-eight tons; average value, $60 per ton, making $2280. Beck & Co. have three cars ready for shipment, and Hennessy & Shay have ten tons. The Mendota tunnel is eighty-eight feet under cover in solid rock. The total length from the starting-point is 100 feet, all in solid rock, twelve feet having been in open cut, to secure a face.

TISHOMINGO.—In this Sherman Mountain property, a party of six has leased the shaft. It started sinking on a foot of lead ore that runs 60 ounces silver and 45 per cent lead.

VIRGINIA CITY.—The managers of this property have concluded to sink the new fifty-foot shaft from the tunnel level considerably deeper. They are accordingly raising the shaft to the surface, a distance of about sixty feet, intending to erect a whim and push the sinking as rapidly as possible.

GARFIELD COUNTY.

Dotsero is the name of a new metropolis that has recently sprung up. The town is located at the junction of the Eagle and Grand rivers.

HINSDALE COUNTY—RED MOUNTAIN DISTRICT.

In the immediate vicinity of this district are the following mines, many of them paying and all capable of shipping pay ore: The Congress, Silver Belle, Senate, Silver Ledge, Turquois, American Girl, Champion, Excelsior, Charter Oak, Treasure Trove, National Belle, Hudson, Enterprise, Galena Lion, Albia, Genesee, Yankee Girl, Orphan Boy, Guston, Robinson, Lily, Holiday, Prescott, Albany, Jed, H. A. W. Tabor, Bonanza King, John Wilson, and Tag End. These mines are all developing, and when the snow, which is quite deep, disappears, the activity will be remarkable. The Yankee Girl has two shafts. No. 1 is 30 feet deep, and is cut by a cross-cut, through which the ore is dumped. The shaft is continued. No. 2 is 90 feet deep, to which the cross-cut is also extended, and each shaft is in solid mineral, the body being from ten to fifteen feet across. Since November, this mine has shipped 1300 tons. The ore averages ninety ounces in silver and forty per cent lead, with a liberal per cent of copper, and the value increases with depth. The Orphan Boy, a parallel lode 150 feet west, owned by the same company, and a cross cut with levels, will connect them as developed. The Orphan Boy vein shows from four to six feet in width, and is widening.

LAKE COUNTY.

Late Leadville exchanges report the following:

CHRYSOLITE.—Since last October, the property has again been self-sustaining, and during the month of March of this year, the yield reached a figure sufficiently large to leave some profit. During April, the surplus returns amounted to about $12,000, and a few days ago Manager Clark made a transmission of money to the New York office, consisting of a draft for $15,000. During March, the mine sold to the smelters 832 tons of ore, netting $25,499; an average of $30.64 per ton. For April, the shipments from the mine were 696 tons, netting $24,555, or an average of $35.23 per ton. The shipments for thirty days in May show 965 tons, and the ore being of better grade than during the two previous months, the returns will exceed $30,000, and permit another remittance to New York. The present resources of the company's mines in ore in sight are limited; but the prospects of opening up new ore-bodies are worth something, while the old workings of the mine will continue producing for an indefinite period yet, but no great advance on the present production can be anticipated. The exploration-work of the mine is confined mostly to the incline starting on the third iron from the foot of the Colorado Chief No. 2 shaft. This body of iron ore occurs as an interstratified vein, and is situated near the center of a stratum of Silurian limestone seventy feet in thickness. The ore consists of oxide of iron and manganese, quite siliceous, and also containing some lime. The mineral presents a quite different appearance from the iron found in the upper workings of the Chrysolite, and it may be safely said that its character and composition are not very favorable to mineral of paying grade. Some ore has been obtained in pursuing this work, but it was found mostly filling vuggs in the iron, and showing no continuity. Occasionally scattered cubes of galena are also found in dark, hard iron, but it is seldom that seams of lead ore are encountered. The incline from the Colorado Chief shaft leaves the perpendicular shaft at 200 feet from the surface, and starts on an incline of 75 degrees from the horizon, toward the Roberts shaft, located 400 feet to the northeast. At 210 feet, the workings of the Sliver shaft are passed, some distance below the old developments about the Sliver. The incline then continues forty feet farther, where its face is now in worthless iron ore. At the point where the incline passes beneath the Sliver workings, a rise was made, showing the following formation: Third iron, 16 feet; parting quartzite, 12 feet; second iron, 10 to 14 inches; block porphyry, 62 feet. This carries the rise up to the old Sliver workings where the upper ore-body of the Chrysolite formerly existed. In addition to the prospect-work in progress from the Colorado Chief shaft, the manager is employing quite a force in exploring the territory of the company through its old workings, and also into new sections, particularly to the north and west, with varied results. A mill was recently erected, and all the waste and low-grade ore-dumps are carefully sampled with the view of ascertaining their silver contents and other features for guidance in the proposed erection of a concentrating mill. Up to the present time, the company has recovered from its old waste and low-grade ore-dumps 197,507 ounces of silver and 507 tons of lead, the result of jigs and hand-sorting, done on tribute.

CLIMAX.—It is reported that the lessee is meeting with unusual success in working the Montana shaft. A large force of miners is employed, and considerable high-grade ore is extracted.

COLORADO PRINCE.—The stamp-mill belonging to this company has been taken down in South Evans Gulch, and is in course of removal to Twin Lake Mining District for re-erection.

GREEN MOUNTAIN.—It is reported that this company has just leased its properties, located on Ball Mountain, surrounding the Green Mountain mine.

HUMBOLDT.—A great deal of work is doing on the properties of this company, situated on the south side of Carbonate Hill. The Humboldt and Gold Leaf lodes are worked by lessees, and the Thistle is developing by the company.

LITTLE CHIEF.—A drift has been driven from the 186-foot level of the Daly shaft eastward to the eastern line of the Little Chief claim, and then northward on the eastern side-line of the Little Chief for a distance of 250 feet. The face of the drift here is in fine-looking iron. A rise was made from the breast of the north drift, and for fifty feet the rise continued in fine-looking iron, then cut through some medium-grade ore, and finally broke into a stope made by the O. K. lessees, who were found trespassing on the territory of the Little Chief. Investigation showed a stope about twenty-five feet in length, seven to eighteen feet high, and four to ten feet wide. The breast of the stope showed iron, galena, and lead carbonates, carrying considerable silver. The streaks were quite strong, and the entire stope is supposed to have contained rich ore. Several specimens were taken from the walls of the stope and an assay made, returning thirteen hundred and odd ounces in silver to the ton.

LITTLE PITTSBURG.—A drift has been driven east to the Amie line, and is now driving to the north of the line, with fair indications of soon cutting iron. The old workings of the lode proper are worked on tribute by F. B. Grant & Co., who began operations recently. The eastern portion of the old workings of the discovery claim was leased to Hereford & Co. about a fortnight ago. Considerable dead-work has been done so far, but pay-work will soon be in order.

Mr. Hawley, formerly with the Grant Smelting Company, and more recently superintendent of the Little Sliver, resigned yesterday, and has accepted the position of metallurgist with the Manville Smelting Company, which will start up the Elgin smelter in about a week.

PARK COUNTY.

FREELAND.—Twenty-eight men have been discharged from the Freeland mine and mill, twenty-four from the former and four from the latter. This reduction is owing to the fact that during the past year development has been carried on to a large extent, and that now the extraction by stoping of the higher-grade ores required a smaller force of men without diminishing the value of the output.

DAKOTA.

Owing to the spring floods, things at Deadwood, and, in fact, throughout the hills generally, are rather dull. The recent cave in the Terra (Deadwood-Terra) did not injure any one. Ten floors went down. The necessary repairs incident to the late flood will be made on the Homestake railroad immediately, when

Digitized by Google

the Caledonia will be furnished with wood, and operations will be resumed. Work on the lower winze was recommenced recently.

CALEDONIA.—The superintendent reports for the week ended May 20th: On the 18th, all men were discharged with the exception of force enough to pump out the mine. A heavy rain fell on the 17th, and caused water to rush into the mine to the depth of three feet, at which we kept it. The roads and railroads are so washed out that wood can not be brought in here. Think it will be about two weeks before we can resume milling. Shipped 671 ounces gold—about $11,500. May 27th, he reports: We have worked 12 men per day at the mine for the past week pumping water, overhauling machinery, and doing other necessary work. The mine is now clear of water, and we resumed sinking the winze last night. We expect to secure wood by the 29th, and will start the mill immediately.

IDAHO.

VALLEY VIEW.—The Wood River *Times* says that this mine has paid its way from the grass-roots. The developments consist of a tunnel 225 feet in length, five cross-cuts about 20 feet long each, two rises, and an incline-shaft or winze. The cross-cuts are run from the tunnel, two on each side, at distances about 20 feet apart, and all show ore. The width of the vein-matter is very great, probably exceeding 50 feet. The ore is of high grade, carrying an average of 265 ounces of silver and 72 per cent lead. Some 60 tons of second-class ore are on the dump, and there are large reserves in the mine.

MEXICO.

GUANAJUATO.—A new mining company has been organized, known as the International Mexican Mining Development Company, on a basis of $4,000,000, divided into 40,000 shares of $100 each.

MICHIGAN.

INDIANA.—It is claimed that this company has made a sale of 5000 tons of ore at $5.25 on the cars, and can sell its entire product for the season at the same price.

LAKE ANGELINE.—The management has sold the entire season's product, the shipment of which has been commenced. The ore is from the newly opened deposit, and a very fine quality of soft hematite.

QUINCY.—The ledge has been struck, at a depth of 55 feet, where ore of better quality than hitherto found in that vicinity was obtained.

MONTANA.

DEER LODGE COUNTY.

PHILLIPSBURG.—According to a correspondent of the Butte *Daily Miner*, the placer mines of this locality will soon be heard from. The Granite mine is looming up. The header of the lower tunnel now stands in six feet of 80-ounce ore. A large force of men is busily at work opening the new road to Hasmark, to connect the mine with the Algonquin mill. The Hope mill is running steadily. The mine keeps the batteries supplied, besides holding a reserve on hand. The diamond drill, intended to prospect the mines of the Hope Company on Hope and Apache hills, is testing. In the San Francisco, the face of the tunnel shows over three feet of ore, assaying 90 ounces and better. This mine lies in the granite, just over the contact. The owners of the Virginia, Elgin, Stonewall, and Lady Mary mines in the granite are preparing for immediate work.

JEFFERSON COUNTY.

AMAZON.—Contracts have been made for 200,000 bricks for the roasters and smelters and for a large amount of lumber for the buildings. These works will be pushed to completion during the present season.

MADISON COUNTY.

ALTA-MONTANA.—According to the Helena *Independent*, there is a project on foot looking to the removal of these works to Helena. The principal reasons for so doing are, that the iron ore and lime-rock used as flux at present have to be hauled from Helena to the works at great expense, and on finishing the railroad, coal for fuel will be laid down here at rates so low as to greatly reduce the cost of smelting.

The Rochester Mining District is just now attracting considerable attention, and the indications point to renewed activity in that section during the present season. The sale is reported of a fourth interest in each of the three properties known as Magna Charta, Garfield, and True Fissure, for the sum of $10,000, to Eastern parties.

SILVER BOW COUNTY—SUMMIT VALLEY DISTRICT.

ANACONDA.—It is said that this company has invested upward of $1,000,000 in the development of the Anaconda and St. Lawrence mines, in the purchase of machinery, the erection of buildings, and in buying fuel.

The present prosperity of the mining interests of Summit Valley District, says the *Inter-Mountain*, is of an extremely gratifying character, and is beyond all dispute. The mines, mills, and smelters are all in profitable operation and running in full blast. Two hundred and twenty-five stamps are pounding merrily away on pay ore, and the output of our silver mines is limited only by the capacity of the mills to treat their product. The four smelters are daily reducing to a marketable form between 250 and 300 tons of high-grade copper ore, and at least 50 tons of crude copper ore are shipped daily to Baltimore or Swansea. The indications are all favorable for an output this year of a total value of between $9,000,000 and $10,000,000. Fully 2500 men are given constant employment at remunerative wages in the mines, mills, and smelters of the district.

POSER.—The new strike in this mine, the property of the Silver Bow Company, is of even greater importance than was at first supposed. The 100-foot east shaft, which follows the vein from the surface, shows good ore all the way down. At the bottom, a cross-cut showed the pay-streak to be fifteen feet wide. Drifts have been started east and west, and an ore-breast twelve feet wide is extracting, three feet of the pay ore-body being of rather low grade. The remaining 12 feet, however, assay from $50 to $100 per ton.

PROVIDENCE.—This mine, situated near Lincoln Gulch, on the Big Blackfoot, yielded 60 ounces of gold, the result of a few days' run of the ten-stamp mill belonging to the company owning the mine.

NEVADA.

ESMERALDA COUNTY.

MOUNT CORY.—A mill to be provided with three sets of Krom rolls is to be put up, and probably a leaching plant will be built.

SAFFORD DISTRICT.

ONONDAGA.—This mine has been stripped on the surface along the ledge a distance of 800 feet, exposing ore varying in width from eight inches to six feet, and in price from $30 to $450 per ton. A force of 20 men is employed at present, and more are to be put on. A new tunnel has been started about 25 feet below the old workings, which is to be run a distance of 800 feet, there to connect with a shaft which is sinking on ore on the northern end of the claim.

ZANOLI.—This claim shows a considerable amount of work. The ledge was first encountered in the shaft at a depth of 30 feet, and has since continued down a distance of 112 feet, varying in width from three inches to six feet, the latter being the present width of the ledge in the bottom of the shaft. The ledge is perfect and well defined, the foot and hanging-walls being plainly discernible throughout the entire depth of the shaft. The ore averages high. A tunnel had been run a distance of 300 feet without success, finally going to a place above, where, at a depth of 300 feet, the ledge was encountered. If present indications continue, it is the intention of the owners to erect a mill on the Humboldt River at Gerald, about a mile distant, where it is estimated ores averaging $12 per ton can be worked at a profit.

NEW MEXICO.

The Santa Fé *New Mexican* states that in the south and eastern portions of Santa Fé County, in the New Placer District, is a section of New Mexico which will become one of the most productive districts in the territory. Its immense area of rich placer ground, its wealthy gold-bearing quartz veins, its fine mines of copper, and its large deposits of argentiferous lead ores all impress one with the greatness of the future possibilities of the district. Although much has been written about the auriferous gravel deposits of the district, their wealth and extent are such that they will continue bearing favorable reference, until steps are taken to work them on a scale proportionate to their magnitude. Almost every gulch or arroya containing deposits of earth is rich in gold; and notwithstanding the drawback occasioned by the scarcity of water, the time must be near at hand when these deposits shall be effectually and systematically worked. Here, it may not be amiss to give a short sketch of the history of the New Placer mines. The discovery of gold was first made in 1842; and within the next five years, the population of the district increased to nearly 4000 souls. Over 1000 persons were engaged in placer mining in the vicinity in 1847. The amount of gold secured has never been even approximately made public; owing to the dangerous and lawless elements, all information as to the product at the time having being kept very quiet. The mode of working was by sinking shafts and drifting, extracting only the richest pay-streaks. In the winter season, when there was snow on the mountains, the miners utilized the snow, melting it with heated stones. When there was no snow, water was brought from springs and the creek at from one to two dollars per barrel, and thus the work was continued. The washing was done in wooden bowls, and carried on under disadvantages; nevertheless it paid well. Many nuggets of considerable value were found, among them one reported that had a weight of eleven pounds and nine ounces avoirdupois, sold for $6000, being at the rate of $16 an ounce troy. At present, several companies are engaged in drilling for water in this section, and it is to be hoped that they will succeed in securing the necessary flow to permit them working on a large scale. Fair pump-wells have been opened; but the supply necessary for working on a large scale has not been secured, though the operations continue with a very sanguine spirit. The quartz-veins of the district are among the richest in the West. The veins as a rule are very strong, and the dissemination of gold through the vein seems general and generous. In the Tuerto Mountains, especially, some of the finest quartz leads to be found anywhere have been opened and worked to some extent, although doing but little just now.

The hitherto abundant supply of iron boulders in the Gallinas Mountain, says the Santa Fé *New Mexican*, utilized for flux in smelting, is rapidly failing.

CUCHILLO NEGRO MINING AND SMELTING COMPANY.—The furnace of this company at Fair View, in the Black Range, is again idle.

IVANHOE.—Work is to be resumed at this mine.

OLD MAN.—This location, at Silver City, is reported to have been bonded for $500,000, the bond including the privilege of exploring the new discovery. Work is reported in progress, and the property is showing up very well. A report just received states that an important strike of horn-silver has been made.

SAN JOSE.—This smelter has been blown in again.

SIERRA BELLE AND SIERRA APACHE.—These mines are to be prepared for large productions. The mines contain a great deal of 50 to 250-ounce ore, which is to be utilized as soon as possible.

UTAH.

FRISCO DISTRICT.

HORN-SILVER.—The bullion shipments for the week ended May 26th were $39,000; previously reported output of this mine for the present year, $1,309,500; present total, $1,348,500.

SUMMIT COUNTY.

CRESCENT.—Mr. J. J. Daly resigned his position as superintendent of this mine recently, and Mr. Peter Porter was elected by the trustees to succeed him.

SAMPSON.—The vice-president of this company reports that 31 tons of second-class ore from the company's mines were sold at Salt Lake City on May 22d at $32 per ton, and that two cars of first-class ore were to have been shipped from the mine on Monday last. Reports from the mine state that on May 18th the east drift of level No. 2, Van Praag incline, had opened into three feet of solid ore, averaging 55 ounces silver per ton and 32 per cent lead, and that the west drift was in one foot of first-class ore running 100 ounces silver per ton and 42 per cent lead. The new shaft is down 60 feet and is to be connected with the vein at a depth of 200 feet by the first of August next.

SILVER MOUNTAIN.—The Salt Lake *Tribune* is authority for the statement that a big strike has been made in this mine, which is situated on Kessler's Peak, Big Cottonwood. For some time past, a tunnel has been run to cut the vein; and when this was accomplished, the tunnel had penetrated the mountain 400 feet. An ore-body five feet wide, the first-class assaying 55 ounces silver, 58 per cent lead, $3 gold, the second class 23½ ounces silver, 26 per cent lead, was encountered. The tunnel is 400 feet below the upper workings, and all the ore can be extracted through it.

WASHINGTON COUNTY—SILVER REEF.

STORMONT.—The superintendent reports: The chamber now opened at twenty-three winze is about fifteen by thirty feet. From above the chamber, about 100 tons have been extracted, and it is reasonable to suppose that the ore will extend enough farther into the solid ground on all sides of this chamber to furnish another 100 tons. Indeed, I shall be disappointed if it does not produce 1000 tons. We are just blasting the ore down and sending it to the mill, and are not yet drifting in it. The fifteen-winze strike shows no change since weekly report of 26th, as we have been stripping the vein, taking down only waste. Assays yesterday showed $108.41 per ton as the average of thirty inches in thickness of ore.

The superintendent telegraphs that a new strike has been made in winze 15. Two feet of $100 ore. Bullion for May, $20,000.

WYOMING.

ALBANY COUNTY.

The *Laramie Boomerang* says that a valuable deposit of iron ore has been discovered near Rock Creek. The iron ore is found in the same hill or "hog-back" containing the soap. It is reddish-brown in color, but gets almost black after being exposed to the air for a time, and is found in lumps something the shape of a kidney, ranging in size from six inches to four or five feet across. It lies about 1000 yards from the railroad track, opposite the eating-house.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, June 8.

This week has been one of remarkable dullness in the mining market. The dealings have been mostly confined to a few stocks, and the Comstocks were the attraction at strong prices. The fancies were all weak, especially Robinson, Sonora, and Decatur. Sonora, as usual, was very actively dealt in, but gradually declined, and closed to-day at its weakest price. Stormont is looming up as an active stock in the market, and indications point to better prices. Sierra Grande was stronger than of late, but the transactions were small. The total number of mining shares sold at all the Exchanges aggregates 196,662, as against 355,084 last week.

The Comstock shares had a fair business at strong prices. California was strong, selling from 29@38 @36c. Consolidated Virginia was moderately dealt in, and was strong; it sold from 58@72@69c. Sierra Nevada had a small business at strong prices, selling from $6@$6.88. Union Consolidated, with a small business, was also strong, selling from $6.25@$7.25. Consolidated Imperial records a moderate business at steady prices, selling from 11@10c. Best & Belcher was dealt in to the extent of 30 shares at $5.25@ $4.75. Sutro Tunnel had a very active business, at irregular prices; it sold from 23@29@26c.

The Leadville stocks were quiet and steady. Amie was quiet and a little weak, selling from 19@16c. Chrysolite had a small business at steady prices; it sold from $1.15@$1.20. Hibernia sold from 3@4c., with a business of 1100 shares. Iron Silver had a small business and was steady; it sold from $3.10@ $2.85, the latter price is ex dividend. Leadville sold at 50c. under a small business, and Little Chief at 40c. Little Pittsburg was irregular, with small transactions, selling from 78@65c.

The Bodie stocks were also quiet and steady. Bodie Consolidated sold from 90c.@$1 under a small business. Standard was moderately dealt in at strong prices, selling from $6.88@$7. Bulwer sold from 60@55c., with a business of 200 shares. Goodshaw was quiet and steady at 5@4c.

The Tuscarora stocks had a small business, and were weak. Argenta sold at 50c. under one small transaction. Belle Isle sold assessment unpaid, and was irregular under a small business; it sold from 20@15@ 22c. Navajo passed its dividend, and in consequence was weak, with a fair business; it sold from $1.70@ $1.50. Independence was quiet and irregular, selling from 35@30@32c. Elko Consolidated was quiet and steady at 18@19c.

In the miscellaneous list, Alice was quiet and steady at $2.75. Bassick sold at $8, the transactions being small. Caribou Consolidated had a fair business at steady prices, selling from 14@13c. Eureka Consolidated was moderately dealt in at weak prices; it sold from $3.45@$3@$3.05, assessment unpaid. Reports state that the company has started up another furnace, principally on account of the increased ore-shipments from Eureka Tunnel and expected shipments from Albion. The Green Mountain stocks were quiet and steady. Gold Stripe sold at 9c. Green Mountain sold from 70@72c., and Cherokee sold at 3c. Homestake was very quiet at $15¼. Horn-Silver was quiet at irregular prices; it sold from $6.63@$6.25@$6.50. Robinson has been quiet and weak; it declined from 83@75c. under a business of 9400 shares. Sierra Grande was moderately dealt in at strong prices; it sold from $1.50@$1.70@$1.65. Stormont has been actively dealt in at strong prices; it sold from 60@72@70c. The stock of the reorganized company has been listed on the Mining Exchange, and the developments at the mines are reported to be good. Expenses have also been reduced.

Alta-Montana has been weak at 4@8c. Bradshaw has also been weak, selling from 33@25c. under a small business. Caledonia records a sale of 100 shares at 80c. Central Arizona sold at 30c. Decatur has become quite weak under an active business, selling from 7@3c. Durango was quiet and steady at 7@6c. Eastern Oregon had a small business at steady prices, selling from 30@32c. Harlem records a moderate business and was irregular; it sold from $1.55@ $1.40@$1.45. Hortense sold at 9c., and Lacrosse at 12c. Oriental & Miller was quiet and steady at 18@16c. Silver Cliff was moderately dealt in and developed a little strength; it sold from 15@20c. Sonora Consolidated had a very active business at declining prices; it sold from 40@29c. State Line Nos. 1 & 4 developed considerable activity at steady prices, selling from 5@4c.; Nos. 2 & 3 quiet and steady at 7@6c. South Pacific sold on Saturd ay at 6c. Monday the stock was struck off the list of the Mining Board, as no attention had been paid to the request of the Board for a statement from the company, and for an explanation of the fact that the books were not kept open for transfer of the stock.

The Trustees of the Gold Placer Mining Company recently issued a notice to the stockholders of the company, stating that unless they came forward and paid a voluntary assessment of four cents per share before June 12th, the property of the company would be sold to pay a claim of about $8000. A meeting of the stockholders was held yesterday at No. 60 Broadway, at which no definite action was taken in the matter beyond the conclusion to make a strong endeavor to raise the money.

An assessment of twenty-five cents per share has been levied by the Tip Top Silver Mining Company, delinquent July 6th.

The Great Boulder Consolidated Gold and Silver Mining Company, of Colorado, in 1880, mortgaged its mines to secure $100,000 of its bonds. In 1881, no interest was paid on the bonds, and the trustees of the mortgage foreclosed it at the request of George William Ballou and Edwin Ford, who held $74,000 of the $89,000 bonds issued. The property was sold, and the trustees bought it in for $60,000 in the interest of the bondholders. Since the sale, the two parties in interest have been unable to come to an agreement, and Judge Donohue has granted an order directing a resale of the property, after the usual six weeks' notice, at the Exchange Salesrooms in this city.

It is said that the stock of the Barcelona Mining Company will soon be listed at the Mining Board. The mine has been leased on very advantageous terms, and the lessees are reported to be taking out ore which will soon be milled and pay the company good royalty.

MEETINGS.

Bonanza King Consolidated Mining Company, No. 29 Wall street, New York City. Meeting of stockholders, June 16th, at two o'clock P.M., to sanction and approve an agreement to consolidate with the Trojan Consolidated Mining Company.

Central Coal Company of Pennsylvania, office of Messrs. G. B. Newton & Co., No. 329 Walnut street, Philadelphia, Pa. Annual meeting of stockholders and election of directors, July 10th, at twelve o'clock noon.

La Plata Mining and Smelting Company, No. 58 Broadway, Rooms 12 and 13, New York City. Annual meeting of stockholders and election of trustees, June 21st, at one o'clock P.M.

Old Dominion Copper Company, No. 72 Broadway, New York City. Postponed annual meeting of stockholders, June 29th, at twelve o'clock noon.

Trojan Consolidated Mining Company, No. 29 Wall street, New York City. Meeting of stockholders, June 16th, at two o'clock P.M., to sanction and approve an agreement to consolidate with the Bonanza King Consolidated Mining Company.

DIVIDENDS.

The Standard Consolidated Mining Company has declared its monthly dividend of twenty-five cents per share, payable June 12th at the Farmers' Loan and Trust Company.

PIPE LINE CERTIFICATES.

As will be seen by reference to our quotations and sales below, the oil market this week has been very active, and the fluctuations have been of a very wild and varied character. Opening on Saturday morning last at $1.19½, oil fell to $1.18½, then took an upward turn to $1.23⅛, closing at $1.20. On Monday, it was weak, and closed with a demoralized market. Tuesday witnessed a still further decline; but on Wednesday there was a reaction, and the "bulls" had the advantage. Yesterday (Thursday) was a field-day for the "bulls," the market being very strong. To-day, the market again turned and lower prices prevailed. The market throughout has been one of manipulation.

No news of an important character has been received from the oil regions during the week. The report of the Pipe Line Company shows an accumulation of oil in its custody from the first of June to the 5th inclusive, of 29,682 barrels in excess of its deliveries. The recent fire near Alleghany City, Pa., destroyed 32,000 barrels, and an assessment of one barrel per thousand has been levied to pay the insurance. Notice has also been given by the Trust Company that all certificates sent to the Clearing-House must be accompanied by a check for $3 per thousand barrels as a guarantee against fire assessments, the Trust Company to return the balance after such assessments have been deducted.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
June 2....	$1.19½	$1.23⅛	$1.18½	$1.20	3,553,000
4....	1.21	1.21⅝	1.14	1.15	4,891,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, June 7.

The market for copper and silver stocks continues to rule dull and inactive. There is so little doing that it is difficult to obtain reliable quotations on the greater portion of the list of stocks dealt in at the Exchange. In copper stocks, Calumet & Hecla, as usual, takes the lead, and in face of the decline of ingot copper to 15½c., shows an advance of $3¼ per share over last week, with sales at $237½. Franklin sold at $10 in small lots, with same bid for it. The May product was 170 tons, and the reports from the mine are all of a favorable character. Quincy is firm at last week's quotation, with sales at $44. A small lot sold to-day at $45, which was also bid for it at the close. The stock is said to be largely oversold and scarce for delivery. The product for May was 261 tons, against 201 tons last year in May. Osceola was quite firm early in the week at $21½, but later sales were made at $20½, closing $20 bid. This stock has been rather more freely offered than usual, and the desire to sell it is the cause of the decline. There were no sales of Pewabic for the week; it is held at $4, with $3 as the best bid. A letter from the Pewabic mine says: The lode in the

Digitized by Google

shaft continues to show a little copper, but not of much value. The lode in the 31st level, both north and south, is improving. It seems as if we should have some ground at these points that will pay to stope. There is no change to notice in any other part of the mine. The May product was 70¼ tons. In other copper stocks there is nothing doing. A letter from the agent of the Huron copper mine says: There is but little change to notice in the mine since my last report, except in No. 10 shaft, where the lode is quite rich in stamp and barrel copper. Work at the mill seems to be gaining a little faster for the past few days than for some time before. On the whole, Huron never looked so well as it does to-day. Huron stock is quiet at $1⅛ asked. The reports from the Douglas Copper Company, of Maine, are encouraging. The company has produced sufficient ingot for a month to pay expenses, and hopes soon to be on an undoubted self-sustaining basis. One ton of ingot copper per day is about the present product of the mill. The management is commendably conservative in what it says of the future and will not encourage the hope of dividends for a couple of years. Meanwhile, it hopes to accumulate a good working surplus. There is but little of the stock offered in the market, $1 being bid for it without calling any of it out.

With the exception of Sullivan, the market for silver stocks is dull and lifeless. Sullivan opened strong, and in the early dealings sold quite freely at $2⅛@$2¼, but later it declined to $1¾, rallied to $2, and finally settled down to $1⅞, which was the closing sale and bidding price. About 2000 shares changed hands. Bonanza sold at $2¼, and Harshaw at 50c. Nothing doing in Catalpa or Crescent.

At the Boston Mining Exchange, trading is confined to a few specialties, and prices are generally unchanged.

3 P.M.—There was was no change in the market this afternoon, which was dull as ever. Harshaw sold at 50c. and Quincy advanced to $46. Bonanza, $2¼ bid, $2⅛ asked. Catalpa, $50@$55. Crescent, 25@30c. Sullivan, $1⅞@$2. San Pedro, 35@40c. Calumet & Hecla, $287 bid. Franklin, $10@$10½. Osceola, $20@$20¼. Pewabic, $3@$3¾. Quincy, $45½ bid.

BULLION MARKET.

NEW YORK, Friday Evening, June 8.

The London market comes weak, and the tendency would seem to be toward somewhat lower figures.

DATE.	London	N. Y	DATE.	London	N. Y.
	Pence.	Cents.		Pence.	Cents.
June 2.	50⅛	109¾	June 6.	50⅛	109¾
4.	50⅛	109¾	7.	50⅛	109¾
5.	50⅛	109¾	8.	50 1-16	109⅝

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended June 8th, as compiled from various sources, amounted to $174,000, as against $117,000 reported for the previous week. The receipts from January 1st, 1883, to date are $5,409,713.53.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended June 2d	$154,000
Corresponding week last year	502,700
Since January 1st, 1883	5,845,911
Corresponding period last year	29,157,548

Imports.

Week ended June 2d	$24,006
Corresponding week last year	18,426
Since January 1st, 1883	6,712,939
Corresponding period last year	1,782,653

Foreign Bank Statements.—The governors of the Bank of England, at their weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 4 per cent. During the week, the bank gained £329,000 bullion, but the proportion of reserve to its liabilities was raised only from 35¼ to 35¾ per cent, against 48¼ per cent at this date a year ago. To-day, the bank made a further gain on balance of £33,000 bullion. The weekly statement of the Bank of France shows an increase of 1,200,000 francs gold, and a loss of 825,000 francs silver.

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14½ per cent, to arrive at actual value.

MINES.	States.	Month of April.	Year from Jan. 1st, 1883.

METALS.

NEW YORK, Friday Evening, June 8.

Copper.—The event of the week has been the sale by the principal lake producers of from 18,000,000 to 20,000,000 pounds at private terms. As to the details of the transaction, nothing but vague rumors are as yet current. A large portion of it—some say all—has been taken by manufacturers, the delivery to extend over the next five months. It is stated in other quarters that some of it was for export. The price is given as 15c., while some of it brought 15⅛c.

For jobbing lots, it is not possible just now to do better than 15⅞c., but of course there is little buying, and for a long time to come there will be little movement in lake copper. Meanwhile, we must record also export sales of upward of 3,000,000 pounds of Arizona copper, details not having been made public as yet. The market has not settled down sufficiently after these transactions to permit of any statement of its condition. We quote nominally Lake 15⅝@15¾c., and other brands 14@15¼c.

Should it prove correct that the Lake companies have supplied the principal consumers with the bulk of their requirements for some months to come, there can be no doubt that values of other brands must recede a little more. There is reason to believe that a certain, though perhaps small, quantity of lake copper, produced by the smaller mines, will find its way into the markets and will compete with the other brands, of which a large proportion will have to seek a foreign market, unless our home demand picks up. Producers will therefore watch the foreign markets more closely than ever, and thus far the outlook is encouraging. Considerable eagerness has been shown by foreign buyers to take Arizona and other metal produced in the West, and values have thus far been fairly well maintained. England cables £69 10s. f. o. b. for Best Selected, and £64 10s. f. o. b. for Chili Bars.

Tin.—Business has been dull during the week, the market closing nominally 21⅜c. for Straits, 21⅝c. for Australian, 21⅞@22c. for Lamb & Flag, and 22c. for Banca. England cables lower, £94 10s.

Lead.—The market has been dull and lifeless, but has been well maintained. Transactions are on a moderate scale, the closing quotations being 4·45c. for Common and Refined.

Messrs. John Wahl & Co., of St. Louis, wire us as follows to-day:

Our market is firm. Sales will not aggregate 200 tons of Refined, at 4·13c., and 160 tons of Chemical at 4·12½c.

Messrs. Everett & Post send us the following dispatch to-day:

We have no change to report. Our market is quiet and steady at 4·15@4·17½c. Two hundred and fifty tons of a special brand sold at 4·20c.

Spelter.—The market has weakened, and we hear of sales, in a small way, at 4·45@4·50c. for good domestic brands.

Antimony.—A large transaction has been recorded during the week at private terms. We quote Cookson's 10¾c., and Hallett's 9¾c. for jobbing lots.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, June 8.

At the Metal Exchange, there were two tickets in the field, one headed by Theodore Sturgis for President, called the "Wall street ticket," it being favored by and favorable to the members of the old "Wall Street Exchange;" and the other headed by T. Delafield for President, and supported generally by the members of the old Pearl Street Exchange. The latter proved successful. Mr. Delafield was elected President by a vote of 113, to 59 for Mr. Sturgis; Frank Dickerson Vice-President by a vote of 172, to 52 for George V. Tompkins; and Mr. Carl Mayer Treasurer by a vote of 154, to 70 scattering. The contest for Secretary excited the most interest. Mr. Edward J. Shriver was elected, receiving 182 votes, to 42 for Mr. William Allen Smith. The following is the rest of the ticket elected: *For Managers*—John C. Cook, Joshua Hendricks, Theodore Sturgis, John T. De Blois, Elliot F. Driggs, William P. Tilton, B. F. Judson, John J. Williams, E. P. White, A. W. Humphreys, H. B. Moore, A. G. A. Harnickell, D. Houston, E. S. Wheeler. *For Arbitration Committee*—D. Thompson, C. E. Maxwell, E. A. Caswell, Daniel F. Cooney, Austin G. Gorham.

American Pig.—Early in the week, the Thomas Iron Company followed openly the example of other companies who had been quietly, as we reported in our last issue, selling No. 1 Foundry here at $20, and during the week that company has closed contracts for season's delivery with the regular customers for upward of 9000 tons of Nos. 1 and 2 at $20 and $19 respectively. No. 1 is fairly steady at that price, but No. 2 is weaker. We quote Foundry No. 1 at $20@$21 for good to choice brands; No. 2, $18@19; and Gray Forge, $17.50@19. Bessemer pig is quiet. England quotes, per cable, 50@51s. Spiegeleisen is moving off with a fair demand, particularly so far as the higher grade is concerned, fetching $31@$31.50. Foreign spiegel is only in limited supply, while low grade, 10 to 12 per cent metal, finds few buyers.

Scotch Pig.—Very little is doing, as the market for American pig is not such as to warrant heavy or even light purchases of Scotch pig. Quotations are almost entirely nominal as follows, ex ship: Coltness, $24@$24.50; Glengarnock, $22@$22.50; Langloan, $23.75@$24; and Eglinton, $21. Warrants are cabled to-day to the Exchange, 47s. On June 6th, the Glasgow quotations received at the Exchange were: Coltness, 61s. 6d.; Langloan, 61s.; Summerlee, 59s. 6d; Gartsherrie, 57s. 6d.;

Digitized by Google

Glengarnock, 54s.; and Eglinton 48s. Freights are 7s. 6d.

Rails.—The mills are well supplied with orders, though it is generally understood that the business was secured by making concessions. Now, however, $38 at mill is the ruling quotation. England cables £4 15s.

Old Rails.—There is nothing of interest to report. Business is dull and quotations remain nominally $22.50@$23 for Ts.

Scrap.—Dealers are generally so well supplied that they are entirely indifferent. Most of them are unable to market their stock at any thing like remunerative figures, and Scrap is therefore neglected at $23 50@$24 for No. 1.

Pittsburg. June 7.

The settlement of the labor difficulties in this city has strengthened the chances of the blast-furnace interests for selling the current output at firm prices. Gray Forge is moving slowly at from $17@$18; Foundry, $19@$21; Bessemer, $21@$22. The commission men report improving inquiry from manufacturers, who, in anticipation of a strike, permitted stocks to run down, and are now virtually without material. There is no assurance given, or possible to be given, that the mills will continue in operation all summer. The threats of a suspension developed an encouraging activity for the past three or four weeks, in all branches of the finished iron trade, and consumers being now fairly supplied for at least thirty days, are not expected to purchase with any activity for that time. The fact that the producing capacity is in excess of probable requirements points to overproduction, to a declining tendency, and then to a restriction. The iron trade regrets the lack of harmony in counsels, but places the responsibility on those who sought to profit by the suspension of iron making.

Small sales are made at 2@2·10c. for Refined iron. Nails continue active. Muck Bars are under good inquiry at $34.50. Wrought Pipes are 70 and 10 per cent off. Boiler tubes, 55 and 5. Oil Well Casing, 45@50c. per foot. Tubing, 15@16c.; fair activity. T rails will sell at $22@$22.50. Sales of between three and four thousand tons have just been closed at these figures. Buyers of steel rails are placing orders with more confidence for summer and early fall delivery. Prices are firm enough to keep large buyers back, as desired concessions can not be obtained.

Steel rail requirements are expected to develop during the summer, and rail makers look for firmness and an improving demand throughout the year. In merchant steel there is a lull, but mills continue in full operation.

Cleveland. June 6.

Trade for past week has been fairly good and a decidedly better feeling shown since the 1st instant. There is a more settled and confident feeling in the trade, and a large amount of mill iron has been sold within the past two or three days, as mills, in anticipation of the strike, had run stock completely down. Foundries generally have a good amount of work, and now that they know about what to figure on, are buying ordinary size lots, instead of pursuing the hand-to-mouth policy that has for some time ruled. While we can not note any advance in price, yet there is a firmer feeling and current prices are readily obtainable. We quote:

No. 1 Bessemer	$22.00@$23.00
" 1 Foundry, all ore	21.00@ 22.00
" 1 Foundry, cinder mixture	20.00@ 21.00
" 1 Soft Foundry	20.00@ 21.50
" 1 Open Silvery	19.50@ 20.00
Mill irons	18.00@ 19.00
4 months f. o. b. cars furnaces.	
Nos. 1 and 2 Charcoal	$24.00@$26.00

COAL TRADE REVIEW.

NEW YORK, Friday Evening, June 8.

Anthracite.

The anthracite coal trade has relapsed into a state of the most absolute dullness. A few inquiries are made by dealers who want to buy coal for June and July delivery at present prices, with a view to guarding against the threatened increase in July. Thus far, these offers are declined. The companies insist that they mean to put up prices in July, and will be ready to restrict sufficiently to force the market to take the coal at the advanced figures. Until now, however, it can not be said that the announcement of this programme is frightening buyers much. On the other hand, the companies are not showing signs of weakness, but there is considerable other coal pressing upon the market. Manufacturers are cutting down their requirements to narrow limits, and the general depression in business, which will not probably be relieved to any extent during the present month, is telling on the consumption of anthracite coal, notably in the Eastern States. A spirit of extreme caution prevails in all business circles, and the movements of some of the anthracite carrying companies are not regarded with much favor in financial circles.

The following is an abstract of the minutes of the meeting of the Western Anthracite Joint Committee, held in this city last week:

As questions were continually arising, during the intervals between the meetings, that required prompt action, it was thought expedient to appoint a committee to whom such questions could be referred. The following resolutions were accordingly adopted:

Resolved, That an Executive Committee of five be appointed (one representative of each of the five competitive interests), whose functions and duties shall be to act in the interim between the meetings of the Coal Committee upon all matters that may be submitted to them, and they shall report their action to the next succeeding meeting of the Joint Committee for approval.

Resolved, That the secretary of this committee be appointed Secretary of the Executive Committee, and that he communicate to the members of this committee any action taken by the Executive Committee; and further, that the Executive Committee be authorized to invite any members of this committee to attend their meetings.

Pursuant to the above, the following persons were appointed such committee: Messrs. Holden, Frisbie, Sayre, T. M. Richards, and Stickney.

After a general discussion as to the condition of the trade, etc., the following resolutions were adopted:

Resolved, That the prices, as fixed for coal on cars at Chicago, apply to all coal going out of Chicago *by rail*, and that the same price shall apply to all coal on cars shipped from Racine or Milwaukee.

Resolved, That the circular prices of coal, as established by this committee, shall be held to apply only to sales to dealers regularly established in the business, and to manufacturers for their own consumption, and that sales to all other parties shall be at *fifty* cents per gross ton above the circular prices.

Resolved, That sales of coal for municipal purposes, either directly or indirectly, through the medium of local dealers or otherwise, shall be upon the same footing in all respects as any other business, and that no deviations from the prices and terms of sale as fixed by this committee shall be made in consideration of such municipal sales.

Resolved, That *ten* (10) cents per ton be added to the regular car prices, for coal screened into wagons for local delivery in Buffalo.

Resolved, That the fixing of prices on lump coal be referred to the Executive Committee.

Resolved, That the fixing of prices to points not yet arranged be referred to the Executive Committee, who shall promptly transmit the figures to all parties in interest.

Adjourned to meet at the Gilsey House, in New York, on Wednesday, June 27th, at ten o'clock A.M.

JOSEPH J. ALBRIGHT, Chairman.
W. E. STREET, Secretary.

Bituminous.

Absolute stagnation characterizes the bituminous coal trade. The manufacturing demand and the quantities supplied to steamers have fallen off very much, and we hear of little or no business. We quote, alongside, nominally, for Clearfield, $4@$4.25; and for Cumberland, $4.20@$4.40, according to quality.

Horsford's Acid Phosphate
Drank With Soda Water
is delicious. All druggists have it. It is refreshing and cooling. Try it often!

For Sale.
150 volumes in German on mining engineering, all new and handsomely bound. Will be sold at less than cost in Germany. Send for Catalogue.
P.O. Box 232, Westchester, Pa.

ROSE POLYTECHNIC INSTITUTE, TERRE Haute, Ind.—A School of Engineering. Mechanics, Civil Engineering, Chemistry, and Drawing. Manufacturing machine-shops, laboratories, library, cabinet, and models. Address, till September 1st, S. S. EARLY, Esq., Sec'y. After that date, CHARLES O. THOMPSON, Pres.

HOLBROOK, F. N.,
Mining Engineer,
SUPERINTENDENT MINING DEPARTMENT OF THE CORRALITOS COMPANY, CORRALITOS, STATE OF CHIHUAHUA, MEXICO

TIP TOP SILVER MINING COMPANY.
Location of principal place of business, San Francisco, Cal.
Location of works, Yavapai County, Arizona Territory.
NOTICE IS HEREBY GIVEN, that at a meeting of the Board of Directors, held on the 29th day of May, 1883, an assessment (No. 6) of twenty-five (25) cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, Room 44, Nevada Block, No. 309 Montgomery street, San Francisco, California, on all certificates of stock issued at San Francisco, and at the Farmers' Loan and Trust Company, No. 26 Exchange Place, New York City, on all certificates issued at New York.
Any stock upon which this assessment shall remain unpaid on
FRIDAY, THE SIXTH (6th) DAY OF JULY, 1883,
will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on MONDAY, THE SIXTH (6th) DAY OF AUGUST, 1883 to pay the delinquent assessment, together with cost of, advertising and expenses of sale.
By order of the Board of Directors.
HENRY DEAS, Secretary.
Office: Room 44, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

MAPS.

ARIZONA AND NEW MEXICO.—This Map shows all the Township Surveys, Private Land Claims, Post-Offices, and Settlements. It also exhibits the Explorations of other Government and Private Expeditions, including the facts developed by the Surveys for the Routes of Projected Railroads, etc. 1881. Scale, one inch to thirty three miles. Colored, 24×17 inches. Pocket form, $1.

COLORADO.—Topographical and Township Map of the State. Compiled from U. S. Government Surveys and other authentic sources, by Louis Nell, Civil Engineer. By means of symbols, the following mass of facts is graphically shown: Railroads in operation; Railroads chartered or in progress; Wagon-roads; Wagon-roads proposed; Trails; Drainage dry during the greater part of the season; County-seats; Post-offices; Villages; Townships subdivided; Townships surveyed in outlines; Contour-lines, with vertical intervals of 1000 feet; Altitudes in feet above sea-level, by barometer observations and by spirit-levels; Private grants; Military reservations; Indian reservations ceded to the U. S. Government; Arable land, with irrigation. Tables of Areas of Counties; Astronomical Positions; Arable Land. Scale, 1 inch: 10·5 miles, Size, 31 × 40 inches. Pocket form. $1.50, on thick paper.

THE SAME, AS A WALL-MAP, GREATLY ENLARGED. 1881. Scale, 1 inch: 6 miles. Size, 46×64 inches. Backed on linen, mounted on rollers, and varnished. Price, $6

COLORADO.—Topographical and Township Map of Part of the State, exhibiting the San Juan, Gunnison, and California Mining Regions. By Louis Nell. Substantially same as above. Post-offices, March 1st, 1880. Scale, 1 inch: 8 miles, 1-570,240. Plain sheets for wall, 90 cents.

COLORADO.—Cannon's Map of the Mineral Belt of Colorado. Taken from the Records of the Surveyor-General's Office, and other reliable Official Sources. Showing, in colors, the Mineral Belt, Gold Districts, Silver Districts, Coal Districts, County Lines, and Boundaries of Land Districts. There are also given the Capital, County Seats, Township Lines, Railroads, and Projected Railroads. Scale, 1 inch: 10 miles. Size, 28x30 inches. Pocket form, $1.50; as a wall-map, $2.

SAN JUAN MINING REGION (COLO.).—Kibbe's Geographical and Geological Map of the San Juan Mining Region. 1881. Shows county lines, wagon-roads, stage routes, trials, railroads, cities and towns with post-offices, camps with post-offices, reduction-works, mountain peaks, continental divide. Also (by colors), eruptive rocks, Carboniferous, Cretaceous, Jura Trias. Elevations above sea-level. Scale, one half-inch to the mile. 21×27 inches. Includes, on same sheet, a reduced Map of the rate of Colorado. Printed in colors, with board covers. $1.50.

SAN JUAN MINING REGION (COLO.).—Stockder's Map of San Juan Mining Region, compiled from U. S. Surveys and other Authentic Sources. 1881. Shows county boundaries, district boundaries wagon-roads, trails over mountain passes from river basin to river basin, continental divide, timber-line (11,000 to 11,500 feet above sea-level), etc. Scale, 1 inch to the mile, or 1=63360. 28×38 inches. Pocket form, stiff paper cover, $1.50; or as wall-map, $1.50.

MR. O. D. COTTON, our representative in the Western and Southern district, has changed his address from No. 35 Wiggins Block, Cincinnati, to No. 26 North High street, Columbus, Ohio.

THE American Society of Mechanical Engineers, the record of whose meeting at Cleveland occupies a part of our space this week, is showing all the evidences of a vigorous growth. The meetings are very well attended, and every one present has the air of meaning business. There are a few in older societies of this class who come to meetings because they want to enjoy the social features, and care little or nothing for the technical matters which come up for consideration. It is probably merely a question of time when the Mechanical Engineers will also count such members in their ranks ; for they will soon, if they go on having, incidentally, such pleasant receptions as the one in Cleveland, acquire a reputation attractive to those who can only prevail upon themselves to attend opening sessions.

It is not a matter to be wondered at that in so young a society there should be some minor defects in the organization and conduct of the meetings. Some of the members will ramble ; but on the whole, the discussions during the meetings of the Society of Mechanical Engineers prove a close attention and are vigorous and well sustained. An admirable system is that of preparing, previous to the meetings, printed slips of the papers, and distributing proofs of accompanying illustrations for reference. It is, of course, possible only when members can be induced to prepare and submit their papers in time to be put into type in advance. On the other hand, this system should make it possible to present only a summary of long papers, with a view to saving time and avoiding the necessity of discriminating between members, by dividing the papers into two classes, those which are actually read and discussed, and those which are condemned to be read "by title." The meetings of the Society of Mechanical Engineers will probably at an early date become models for her sister societies. The society is now launched on the tide of success, and gives promise of fully meeting the most sanguine expectations of its founders.

THE RAILROADS AND HIGH EXPLOSIVES.

The position which the different railroads of the country have taken on the question of carrying high explosives is peculiar in many instances. Some of the greatest lines in the country, the Vanderbilt system, the Erie, the Union Pacific, the Michigan roads, and a considerable number of lines in the West, East, and South, decline to carry high explosives under any circumstances. Some are entirely deaf to arguments, while others cut off all discussion by assuming the position that the profit of the business of carrying explosives does not warrant the risk attending it. Upon the latter point, they adhere to notions once formed, and decline to listen to the most liberal offers to afford them the means of forming an opinion based upon experiments carried out by experts of their own choosing. The manufacturers of high explosives above all others are intensely interested in carefully studying every means of avoiding accidents in transit or in use. They have been prompt and conscientious in carrying out instructions framed by railroad officials with a view to making the carriage of explosives safe ; but honest effort ceases when met with such stolid indifference. They have submitted to what in some cases seemed the inevitable, and have in many instances practically abandoned territory in which they did a good trade.

Roughly, about ten million pounds of high explosives are annually distributed among consumers, much of it being shipped over long distances by rail because the points of consumption are far from the centers of production. In some cases, local works supply the demand of important regions, or water routes give access when communication by rail is cut off. Still, the policy adopted by some of the railroads has undoubtedly a tendency to cut off a considerable portion of the scattered trade, and from the manufacturer's point of view is quite a serious matter. It is not our purpose for the present to discuss the question whether as common carriers the railroads have legally the right to refuse to carry any class of goods without showing better cause for such refusal. They undoubtedly have the right to make and enforce such regulations, within reasonable limits, as will protect their own life and property and that of their patrons. They are justified, too, in charging rates of freight which will compensate them for the risk incurred in carrying dangerous freight. They have freely exercised these privileges. They demand from one and a half to double the rates on first-class freight, and are apparently well content with assuming the risk for that consideration, as they have declined proposals on the part of responsible manufacturers to give bonds to pay any damages inflicted upon property in all but those cases where accidents were due to carelessness on the part of railroads. The consideration for the assumption of the risk by the manufacturers was to be, that the rates of freight be the same as those governing the carriage of any ordinary freight, the classification to be on the same basis.

How unfair is the stand taken by the railroads in peremptorily declining to carry high explosives, may be judged from a glance at the records of accidents due to their transportation. The only two cases we know of are the explosion of a car-load of dynamite at Council Bluffs, where the car in question was one in a burning train. It is a difficult matter to explain the cause of this explosion, when facts are on record showing that large lots of dynamite have been consumed in conflagrations of storehouses and shops without causing an explosion. It is believed that in breaking down, some of the iron-work of the car must have been thrust, in a red-hot condition, into some of the unconsumed explosive. A second more recent case happened at Kittanning, Pa. It appears that two persons were amusing themselves in practicing pistol-shooting, making a freight-car their target. The car happened to be loaded with explosive material, and a stray bullet penetrating into the cases exploded them. It will be conceded that the probability of the occurrence of such a chain of circumstances as those leading to the Kittanning accident is not great, and still such happenings strengthen in the minds of railroad officials and the general public the unreasonable fears in regard to high explosives. They will not bear certain treatment, it is true ; but when handled by men of ordinary intelligence, they are less dangerous than many other substances, and notably black powder. There is as much logic in the proceeding of the refractory railroads in declining, as there would be in the action of a State to the crossing of rivers by railroads on bridges, because occasionally trains will drop through them into the water below.

Until now, the struggle on the question of the carriage of high explosives has been conducted by private conference between the manufacturers and the railroad officials. The consumers, it is true, could have no better champions ; but, after all, it is they who have had to carry the greater part of the burden inflicted upon the article by the restrictions of the railroad companies. They are content to pay the manufacturers a fair profit, and to see the railroad companies compensated for the work and the risk of transportation ; but it is too much to ask them to submit to paying for special methods of carriage or go without high explosives entirely, because a few railroad officials are too timid or too indolent to go into the merits of an important question, and prefer to brush it aside by an arbitrary exercise of power.

THE ROANOKE MEETING OF THE AMERICAN INSTITUTE OF MINING ENGINEERS.—II.

The second session of the Roanoke meeting of the Institute of Mining Engineers was held in Rohrer Hall on Wednesday morning, June 6th.

An interesting address was made by Major Jed Hotchkiss, on the Iron Ores of the Virginias West of the Archæan or Eastern Blue Ridge, and on the Coals of the Lower Measures, or Conglomerate Group in the Virginias. The address was illustrated by maps and sections.

The Major talked in his usual entertaining manner. He described at length the different iron ore formations, and mentioned several localities where the ores were in great abundance and of fine quality. He said there was no anthracite coal in Virginia worth a button. He felt obliged to make this emphatic declaration, because Wall Street was all the time starting companies on bogus anthracite coal-beds in this State; and he wanted all the members of the Institute to tell any body who said there was anthracite coal (worth a button) in Virginia that Jed Hotchkiss said it was a lie.

Mr. Edward Gridley, of Wassaic, N. Y., then read a paper on Cast-Iron of Unusual Strength. The iron was made at Wassaic Furnace, Dutchess County, N. Y., from a mixture of two thirds roasted carbonate ore and one third raw carbonate. The tensile strength varied from 39,669 to 47,500 pounds per square inch, with 41,349 as the average of thirteen tests. The roasted carbonate ore contained iron 54·042; manganese, 2·165; and phosphorus, 0·120. The pig-iron was analyzed by Dr. T. M. Drown with the following result: Graphitic carbon, 2·310; combined carbon, 0·780; silicon, 1·307; sulphur, 0·086; phosphorus, 0·294; manganese, 1·512; iron, 93·700; total, 99·989.

Dr. Persifor Frazer read a paper on the Copper Deposits of the South Mountain. He also exhibited a barometer made by Hicks, of London. It was made of aluminium, and was inclosed in a cork case. It was characterized by great lightness, being only about one third the weight of an ordinary barometer.

A paper on the Porosity and Specific Gravity of Coke was then read by Prof. F. P. Dewey, of Washington, D. C.; after which, Mr. E. Gybbon Spilsbury, of Lancaster County, S. C., presented a valuable paper on Gold Mining in South Carolina.

Many of the members afterward visited the Rohrer Iron Company's mines, situated a few miles from Roanoke, where preparations are making to mine on an extensive scale large and valuable deposits of brown hematite iron ore. The Crozer Steel and Iron Company's furnace and the Roanoke Machine-Works were also visited. These latter at present form a most important part of the industrial establishments of Roanoke, and as they are so complete and so convenient in their arrangements and equipments, I give somewhat in detail a description of these works from information kindly furnished by the courteous superintendent, Mr. Charles Blackwell.

ROANOKE MACHINE-WORKS.

Engine-House.—Annular in shape, one half of a circle, or 180 degrees, completed. Radius of outside brick walls, 157 feet. Span of iron, Fink roof-trusses, 64 feet from center to center of pins. The inside wall consists of wrought-iron columns and heavy glazed wooden doors, opening outward. The roof is covered with slate, finished with galvanized iron cornices. There are two principal entrances, one from the Norfolk & Western and another from the Shenandoah Valley Railroad. No doors are required at these, as brick walls carried up to the ridge of the roof completely shut off these passages from the rest of the building, thereby reducing the danger in the event of fire. Twenty pits provide shed room for as many engines. Each pit is provided with a jack for the escape of smoke; and in order to avoid the otherwise frequent renewal, on account of corrosion, that portion of each jack which is above the roof-line is constructed of terra-cotta. One of the pits is supplied with a driving-wheel and truck-wheel hydraulic drop arrangement, for the purpose of facilitating repairs to driving-boxes, and changing of truck-wheels of engines without lifting the engines. The entire shop is floored with two-inch oak plank.

A combined lighting-up furnace and sand-drier is constructed against the outer wall, about the middle of the shop, thus saving the necessity of lighting up engines with wood, and avoiding thereby considerable danger from fire caused by the sparks from the partially consumed wood, and likely to be thrown from the stack or ash-pan while running the first few miles after starting with a train. Each pit has a water-hydrant conveniently placed for the purpose of attachment of hose for washing out and filling up of boilers. On each side-wall of each pit are placed four steam pipes for heating purposes, steam for which purpose is intended to be taken from a stationary engine boiler, at the west end of the machine-shop. Each pit is separately drained into a twelve-inch terra-cotta main drain, and terminating at Lick Run (a small stream in the neighborhood), and provided with two traps for the accumulation and removal of solid matter. The turn-table is placed at the center of the area inclosed within the annular building when completed. It is 75 feet diameter, and of the upper truss type, thus necessitating an extremely shallow pit, the ordinary build of table with deep pit being undesirable, on account of liability to flood from back-water through drains at high stages of the creek. This unusual diameter was decided upon, as the necessity for frogs was thereby obviated and the serious expense of their maintenance and renewal avoided.

A compromise gauge, with two inside guard-rails, suiting both 5 foot and 4 foot 9-inch gauges, is laid on the table, thus serving equally well both the Norfolk & Western and the Shenandoah Valley section of the engine-house. Should necessity arise, the table can be arranged to turn by steam power. About 40 men will be employed in this building.

Smith-Shop.—This is rectangular in shape, 350 feet by 72 feet, with iron roof-trusses, and covered with slate. Additional light and means of escape for smoke are provided by the movable sashes in the louvre, which is 20 feet in width and extends nearly the entire length of the building. It is intended to take the smoke from the various fires by means of two overhead flues to the stack of the machine-shop stationary engine boiler.

Two bolt-forging and heading machines will be used, thus very considerably reducing hand labor. Blast is supplied by a No. 10 Sturtevant blower. Steam-hammer work will also be done in this shop; four steam-hammers of 600, 1100, 1500, and 3000 pounds capacity respectively, and one 3000-pound drop-hammer, being provided. Engine frames and axles will be forged, and truck-bars and other car work shaped, by means of these hammers. Steam for the use of these various hammers is supplied by a continuous pipe leading from the machine-shop boiler at the west end and the two boilers over the two furnaces at the east end. The waste heat from the furnaces is utilized for the purpose of making steam. This shop will employ from 90 to 100 men.

Between smith and machine-shops is located the tube-shop, where tubes will be cleaned, cut, and pieced, the welding being performed by a steam-hammer made expressly for that purpose.

Machine-Shop.—This is rectangular in shape, 381 feet by 72 feet, with iron Fink roof-trusses, and covered with slate. To give additional light and ventilation, movable sashes are placed in the louvre, which extends nearly the whole length of building.

An annex, 28 feet by 19 feet at the northwest corner of this building, contains the stationary engine of 100 horse-power, which drives the machines in this as well as the smith-shop. The engine is of the Hartford Engineering Company's well-known make, with cylinder 14 inches by 24 inches, and will be run at 120 revolutions per minute. Steam will be supplied by a centrally fired Galloway boiler, 7 feet diameter and 28 feet in length, and made by the Edgemoor Iron Company. This is a class of boiler much used in England, on account of economical consumption of fuel and facility of cleaning, and has only recently been introduced into this country. To insure economical consumption of fuel, a brick stack, 140 feet in hight, has been provided. Placed in the engine-room is the Worthington duplex compound steam-pump, with steam cylinders 12-inch and 18-inch diameter, and 10-inch stroke, which takes its supply of water from a 10-inch main laid from the McClanaghan spring about one and three quarter miles distant, and discharges into an eight-inch distributing main, the open end of which is connected with two pine water-tanks, each having a capacity of 50,000 gallons, and erected on the top of trestles 30 feet in hight, at the highest point of Woodland Park, giving, when full, a head of 140 feet above rail level in the yard. Pipes connected with the eight-inch main will distribute the water when desired. To prevent dangerous water-hammer, air vessels will be placed at proper intervals. The machine-shop will contain the usual machines necessary for finishing castings and forgings required in the construction of engines and cars. The principal feature in it is the four-ton walking-crane, running on a single rail the entire length of the shop. Its power is obtained from an endless hemp rope running at the speed of 1800 feet per minute. These cranes are very frequently used in England, but never hitherto in this country. This shop will employ more than 150 men.

Between machine and erecting-shops, the tool-room and offices for master mechanic and time-keeper are located. In the tool-room, machines for the construction of all tools required in the various shops will be placed; also metal and oil testing-machines.

Erecting-Shop.—This is rectangular in shape, 516 feet 8 inches by 64 feet, with iron Fink roof-trusses, and covered with slate. To give additional light and ventilation, movable sashes are placed in the louvre, which extends nearly the entire length of the building.

The erection of new engines and tenders, and the repairs of others, will be carried on at the western end of this shop, which is connected with the engine-house by a three-rail track suitable for both 5 foot and 4 foot 9 inch gauges. This track extends the entire length of the shop. On each side of the central track, and for a distance of 250 feet from the west end of the shop, will be a pit upon which building and repairs will be executed. To transfer engines to the side-pits from the center track, two overhead 25-ton cranes (traveling) will be used, similar to those at Altoona, and as very generally at work in engine-building establishments in England and other parts of Europe. Power to operate these cranes will be obtained from an endless hemp rope, running at the speed of 4800 feet per minute. This rope is driven by a 7 by 7 Westinghouse engine, placed in the southeast corner of the shop and on the top of the wall on which one of the rails for cranes is placed. The engine makes about 400 revolutions per minute. (The sheave for the driving-rope is keyed directly on the engine-shafts. Boiler and tender work will be carried on at the east end of this building; and to save both time and a large force of skilled labor, a set of Tweddelles's hydraulic riveting plant, made by Fielding & Platt, Gloucester, England, has been ordered, which will insure the best possible class of boiler work being made. This shop will employ about 120 men.

The machines required for boiler work are driven by a 12 by 12 vertical engine, supplied by the New York Safety Steam Power Company, and making 120 revolutions per minute. The main driving-shaft is placed about two feet below the floor of the shop, and is coupled directly to the end of the engine-shaft. Both this engine and the Westinghouse engine are supplied with steam from the foundry boiler.

The Foundry.—This building is rectangular, 252 feet by 72 feet, with iron Fink roof-trusses, and covered with slate. Additional light and ventilation will be provided by the louvre, which extends nearly the entire length of the building. Castings for engines and cars will be made in this building, which is constructed sufficiently large for casting 50 car-wheels per day in addition. A brass foundry will be located in the southwest corner. The two cupolas are of the well-known Collian type, and 40 inches and 47 inches internal diameter respectively. Blast for the cupolas will be supplied by a Baker blower with independent engine.

Hydraulic cranes will be employed to handle the wheels when their construction is begun, and to work the stock-hoist. Two or three molding-machines have been ordered, which will save a large amount of time and labor. The shafting for working the bolting-machines, etc., is driven by a 10 by 12 vertical engine, steam for which, as well as for the Baker blower, accumulator, pump and two engines in the erecting-shop, being supplied from a boiler made by Best & Son, Lancaster, Pa. This shop will employ from 50 to 80 men.

Immediately west of the foundry, the building for stores and offices is located. It is 165 feet by 72 feet, constructed of brick, and roofed with slate, affording accommodation for superintendent, draftsmen, and clerks. It will be heated by steam, and will have two hoists for shifting material between the two floors.

Freight-Car Erecting-Shop.—This is an annular-shaped building, 92

Digitized by Google

feet wide and 408 feet diameter over outer brick walls. The roof is made of timber, and covered with slate. One half a circle, or 180 degrees, has been built and finished with a brick gable at each end. A louvre provides ample light and ventilation. A central turn-table, 100 feet in diameter, serves the two entrance tracks and the twenty tracks in the building, each of which latter is capable of holding two freight-cars. The large table is capable of accommodating two freight-cars and a switch-engine at once, thus saving a large amount of time and labor. Steam-power will be employed to turn this table, which is of a similar design to the engine turn-table, and with a shallow pit. This shop will employ from 60 to 120 men.

Planing-Mill.—This is a rectangular building 250 feet by 72 feet, with iron Fink roof, covered with slate, and provided with a louvre for additional light and ventilation. The engine-room is 27 feet 6 inches by 16 feet 6 inches, and the boiler-room and shaving-tower 59 feet by 26 feet 6 inches. The engine, made by the Hartford Engineering Company, is 20 inches by 30 inches, and will make 100 revolutions per minute, developing about 150 horse-power. It is supplied by steam from two under-fired Galloway boilers, each 18 feet 5 inches by 7 feet diameter. Shavings and chips conveyed through a tube from the planing-mill will form its fuel, which will be fed automatically by an endless grate. These boilers are made by the Edgemoor Iron Company. The stack is of brick and 120 feet in hight. The planing-mill will employ from 30 to 50 men.

Lumber-Drier.—This building is rectangular in form, and 70 feet by 39 feet 4 inches, with tin roof, and of the well-known form peculiar to the Excelsior & Chicago drier. Exhaust steam from the planing-mill engine will be used for providing the necessary heat.

Steam Heater.—The machine and erecting-shops will be heated by the exhaust steam from the machine-shop engine. The freight-car erecting-shop will be heated by live steam from a special boiler. The planing-mill will be heated by exhaust steam from its engine.

Water Supply.—A thorough system of water supply has been provided in case of fire, and a trained fire brigade will materially add to the general safety of the works.

The wood-working machines of the planing-mill are of the well-known build of Messrs. London, Berry & Orton.

In the afternoon, a special train, provided by the Norfolk & Western Railroad, conveyed the members to the Upland mines of the Crozer Steel and Iron Company, situated near Blue Ridge Springs. These are the mines from which this company will draw a large supply of ore for its new furnace. The ores are expected to yield fully fifty per cent metallic iron in the furnace. In the evening, an elaborate entertainment was provided by the citizens of Roanoke, at the Blue Ridge Springs Hotel.

A session of the Institute was afterward held in the ball-room of the hotel. Mr. J. P. Witherow read an interesting paper on the New Blast-Furnace of the Crozer Steel and Iron Company. The furnace was built under the direction of Messrs. Witherow & Gordon, of Pittsburg, Pa. Building was begun in April, 1882, and finished May 1st, 1883. The furnace was blown in May 28th. The stack is 70 by 16; hearth, 9 feet diameter; tunnel-head, 12 feet 8 inches; columns, 20 feet above hearth-level, below which they extend 2 feet. The shell or casing is 23 feet diameter at bottom, and 19 feet at top. Double bell, 8 feet 4½ inches external diameter, and 4 feet 4 inches internal diameter, operated by a 32-inch by 68-inch air-shaft, provided with safety catch-rods. The tuyeres are seven in number, with 7-inch nozzles placed 5 feet 6 inches above hearth-level. The furnace is provided with three Whitwell fire-brick hot-blast stoves, 18 feet diameter and 70 feet high, each containing over 20,000 square feet of heating surface. The iron chimney draught-stack is 160 feet by 8 feet. There are ten steel flue boilers; and two Weimer blowing-engines, with steam cylinder 42 inches and 4-foot stroke, and blowing cylinder 84 inches with 4-foot stroke, and each capable of blowing 12,000 cubic feet of air per minute. The steam-hoist is the Crane Brothers' pattern. The stock-house is 75 feet by 150 feet, frame; cast-house, 138 feet by 50 feet by 28 feet, brick, with corrugated iron roof. The engine-house is roofed with a sway-bottom iron water-tank 6 feet deep in center. The furnace will have a daily capacity of one hundred tons. The fuel at present used is Connellsville coke; but the future supply will be drawn from the ovens of the Southwest Virginia Improvement Company, at Pocahontas, Va. The flux—which is a dolomitic limestone—is obtained a short distance from the furnace. The ores used are brown hematites, chiefly from the company's Upland mines, near Blue Ridge Springs, and from the Houston mines, in the Cloverdale ore-belt; the average distance of these mines from the furnace being about fourteen miles. The ores will average 50 per cent in the furnace.

At the conclusion of Mr. Witherow's paper, Professor Hitchcock made some remarks on the Geological Position of the Philadelphia Gneisses, which were discussed by Messrs. Frazer, Ashburner, Rand, Chance, and Sanders.

Professor Egleston announced the death of Professor Gruner, of France, an honorary member of the Institute, and gave a short sketch of his life. Mr. Ashburner spoke of the recent death of Mr. James Parke, Jr., of Pittsburg, and moved that the President of the Institute be requested to prepare an obituary notice for the Transactions of the Institute.

Sixty-six members and associates were then elected. The secretary read the following papers by title: Repairs and Improvements at Cedar Point Furnace, Port Henry, N. Y., by T. F. Witherbee, of Port Henry. Leaching of Gold and Silver Ores in the West, by Dr. T. Egleston. The Schwartzkopf Control and Safety Apparatus for Steam Boilers, by C. A. Stetefeldt, of New York City. The Shelf Dry Kiln, by C. A. Stetefeldt. The Coals of Pocahontas, Virginia, by Captain C. R. Boyd. The Treatment of Slimes, by F. G. Coggin, of Lake Linden, Michigan. Boilers and Boiler Settings for Blast-Furnaces, by F. W. Gordon, of Pittsburg, Pa. The Timber of West Virginia, by Professor S. P. Sharples, of Boston. Notes on the Geology of Alabama, communicated by Dr. R. W. Raymond, of New York City. The Langdon Gas-Producer, by N. M. Langdon, of Chester, N. J. Determination of Manganese, by Magnus Troilius, of Philadelphia. The Geologico-Geographical Distribution of the Iron Ores of the Eastern United States, by Professor J. C. Smock, New Brunswick, N. J. Volumetric Determination of Manganese, by Messrs. Beebe, Colby, and Mackintosh, of New York. Russell's Improved Process of Lixiviating Silver Ores, by C. A. Stetefeldt, New York. Copper Rocks of South Mountain, by C. Hanford Henderson, Philadelphia. Notes on the Construction of Chimneys, by P. Barnes, Elgin, Ill.

Resolutions were then passed thanking the different railroad companies and the citizens of Roanoke and Lynchburg for courtesies extended to the Institute; after which, the meeting was declared adjourned.

On Thursday, a trip was made to the Flat-Top coal-fields, going over the New River Division of the Norfolk & Western Railroad, which has just been opened for traffic. This division starts at New River Bridge, and has its present terminus at Pocahontas, the length of the line being 73·9 miles. It follows the valley of New River for a distance of thirty-seven miles, and then turns sharply to the west and follows East River to its head-waters; thence it crosses a summit to the head-waters of the Bluestone, and it follows this river to the mouth of Laurel Creek, where it strikes the edge of the Flat-Top coal-field; thence up Laurel Creek to Pocahontas, where the Southwest Virginia Improvement Company has opened up a magnificent bed of the finest quality of coal—a coal which is the exact counterpart of the *best* of the Clearfield coals in Pennsylvania.

New River is one of the few rivers of the world which flows almost due north. It cuts the mountain ranges at right angles, making many gaps, which exceed the celebrated Delaware Water-Gap in Pennsylvania. The scenery generally is very grand; indeed, it is difficult to imagine any thing more varied and beautiful.

Going up New River, we passed Eggleson's Springs, an old popular Virginia summer resort, now somewhat fallen into decay, but exceedingly beautiful still, with its magnificent rock scenery.

Less than eighteen months ago, what is now the thriving mining town of Pocahontas was a dense forest. In February, 1882, the Southwest Virginia Improvement Company located its coal mines at this point; giving employment, at present, to about 500 men. It has opened up what is known as the No. 3 or Nelson bed of coal, here 12 feet thick. Already some 6200 feet of gangways have been driven, the main drift being 1600 feet long, 9 feet wide, and 9 feet high. The mine will be worked by the double-entry system of mining; pillars 16 feet, and rooms 18 feet. Nine feet of the coal-bed will be worked out in advance, leaving 3 feet in the roof to be taken out when the pillars are drawn. Two hundred bee-hive coke-ovens, 12 feet by 6 feet, have already been built, having a daily capacity of 250 tons of 48-hour coke, and the ground has been laid off to accommodate 500 additional ovens, which will be built whenever the market demands.

The present daily output of coal is 400 tons, and in six months it is expected to be a thousand tons or more, which amount can be doubled in a comparatively short time. Expressions of admiration were heard on all sides, not only as to the fine quality of the coal, and the great thickness of the bed, but also as to the thorough and systematic manner in which the entire developments had been conducted; and to the able and energetic superintendent, Mr. William A. Lathrop, the credit of this belongs.

After an examination of the mines and coke-ovens, we were handsomely entertained with an elaborate lunch provided by the Southwest Virginia Improvement Company. The banquet-room was tastefully decorated and festooned with evergreens and flowers; and above the door, worked in flowers, were the words, "Welcome, ye Sons of Science!" The occasion was a very happy one, and every one fully appreciated the good things so bountifully supplied.

Our next point was Wytheville, where we spent the night. Some of our number were the guests of the citizens of Wytheville at their private residences; but the majority found comfortable accommodations at Boyd's Hotel. Here we found ourselves the guests of Colonel Boyd, and right royally did he entertain us.

Next morning (Friday), an early start was made for Cranberry. What member of the Institute had not heard of Cranberry before? A special train, on this as on other occasions kindly provided by the Norfolk & Western Railroad, took us over the Norfolk & Western Railroad, and the East Tennessee, Virginia & Georgia Railroad to Johnson City, Tenn., where we found another train, composed chiefly of observation-cars, waiting to convey us to Cranberry. The Cranberry mine, the property of the Cranberry Coal and Iron Company, is located on the north slope of Hump Mountain, Mitchell County, N. C. The mine is reached by the East Tennessee & Western North Carolina Railroad—a narrow-gauge road 3 feet wide, with 40-pound iron rails—34 miles east from Johnson City. The heaviest curves on the railroad are 18 degrees; and the heaviest grade, going east, 150 feet to the mile for two miles, and, going west, 80 feet to the mile for a short distance. The railroad follows first the Watauga River and then the Doe to its head-waters. The scenery is magnificent, and beggars description. At the mine, the elevation is 1500 feet above Johnson City and 3250 feet above tide. The mine is worked by tunnel which goes through gneiss rock, etc., for 220 feet, and then through hornblende and associated minerals to ore. Five or six machine drills are in operation, worked by compressed air. The daily output of the mine is at present 140 tons, and from ten to twelve thousand tons of ore have already been mined, a large proportion of which has been shipped to furnaces in the Lehigh Valley of Pennsylvania. The ore appears to be of good quality, and will doubtless make a first-class Bessemer pig-iron; for all the analyses show it to be comparatively free from phosphorus.

We returned to Roanoke in the evening, greatly delighted with our trip. This ended the regular programme. On Saturday, many of the members availed themselves of the courtesies extended by the Shenandoah Valley Railroad to visit the Natural Bridge and the Luray Caverns; while others accepted the hospitalities of the iron-masters of Wythe County, and visited the famous Cripple Creek ore-belt.

It is the unanimous verdict that the Roanoke Meeting has been a grand success. Never before perhaps in the history of the Institute have the members received a more cordial welcome or been more handsomely entertained.

To the members of the local committees and to the citizens of Roanoke we were indebted, not only for the dinner tendered us at Blue Ridge Springs, but also for numerous lunches (I might almost say a perpetual lunch) furnished on the cars during our excursions, and for their unceasing efforts to make our visit agreeable.

The great kindnesses received by every one will doubtless be the means of keeping the memory of the Roanoke Meeting as ever-green as were the decorations at Pocahontas.

ROANOKE, VA., June 9.

THE CONCENTRATING MILL AT THE O'NEIL MINES, GALENA, KANSAS.

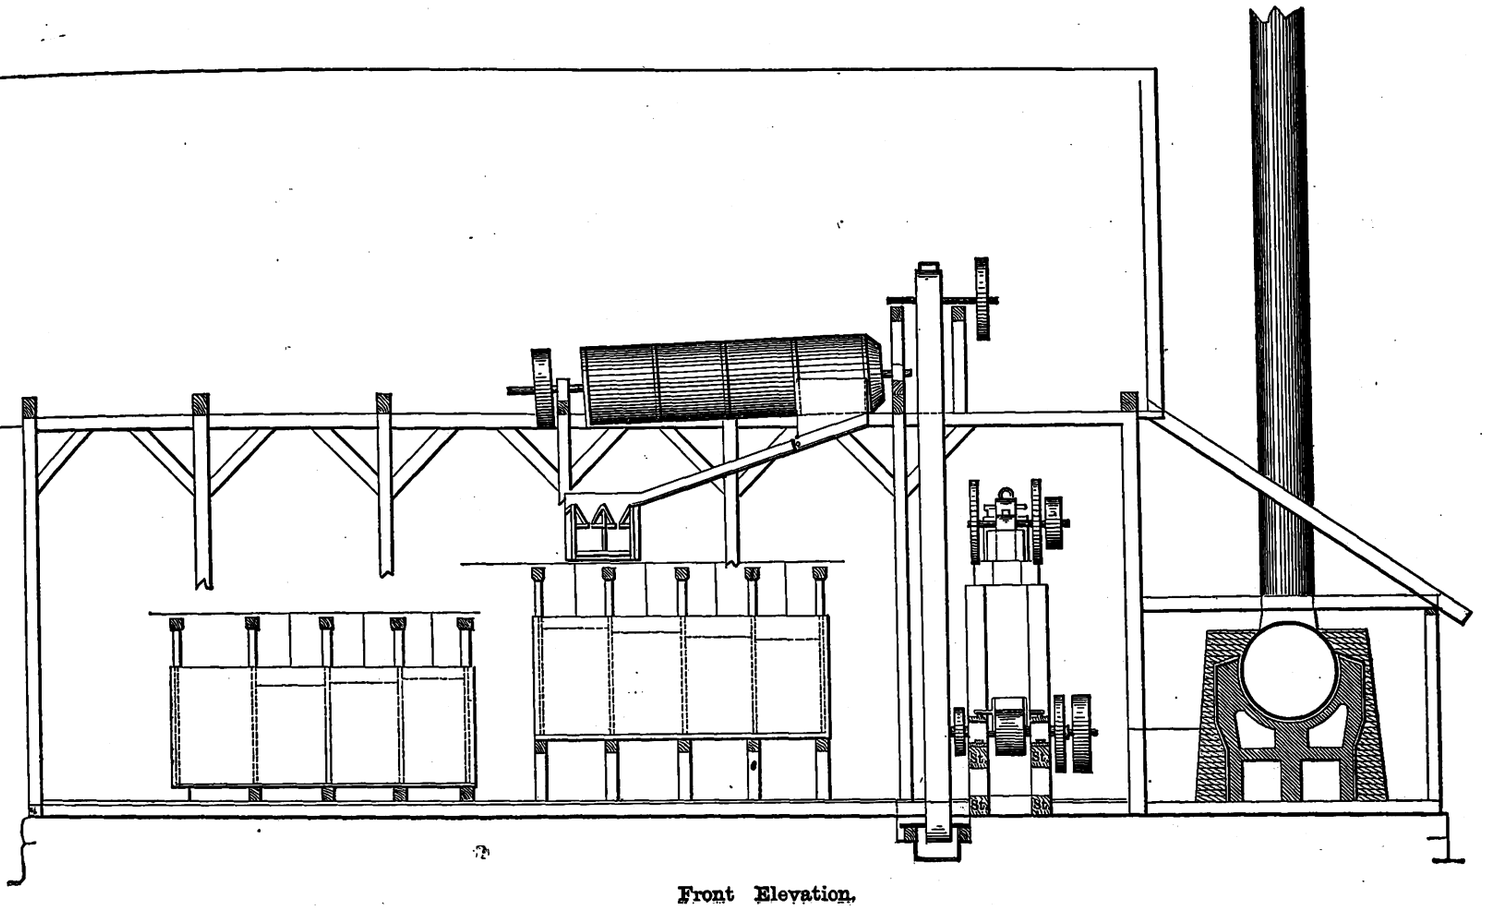
Referring to the "Concentrating of Ores in Southwest Missouri," published in No. 15, Vol. XXXV., page 207, of this JOURNAL, we now give our readers a description and sketch of one of the numerous small and cheap concentrating-works erected in the last few years in the lead and zinc region of Southwest Missouri and Southeastern Kansas, by the Fort Scott Foundry and Machine-Works of Fort Scott, Kansas. These works were constructed and erected under the superintendence of F. de Stwolinski in charge of their mining department.

The concentrator herein described is situated at the O'Neil mines, formerly the Stanley mines, three miles from the town of Galena, Cherokee County, Kansas.

The ores, galena and zinc-blende, occur largely in pockets, with chert and lime-rock. The raw ore has an average of from five to six per cent of galena, and from twenty to twenty-five per cent of zinc-blende.

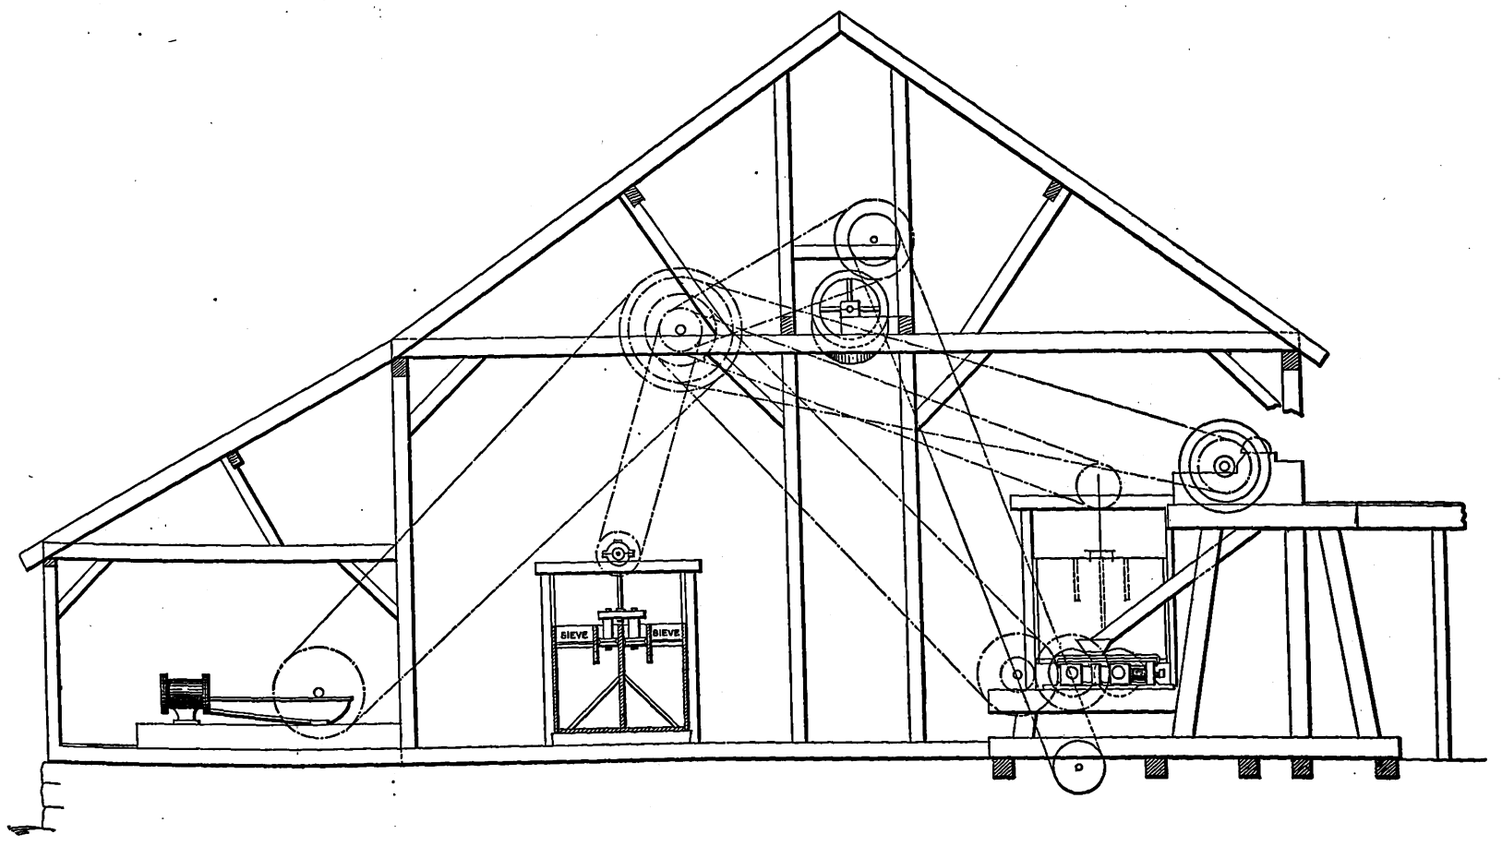
Plan.

The building for the concentrator is 35 feet wide, 44 feet long, and 16 feet in scantling. The boiler and engine are in a small outbuilding, and are inclosed and covered by an extension of the roof of the main building.



The machinery consists of an improved Blake breaker, 7 by 10 inches opening, one set of crushing-rollers 20 inches in diameter and 14-inch face. The tires on the rollers are of very hard chilled iron, and so arranged on their cores that they can be easily replaced when worn out. The springs used are of rubber. The mill contains one elevator, with 12-inch belt; one revolving sizing-screen, having four sections, each 2½ feet long and 3 feet in diameter, made of Juniata sheet-iron and perforated with holes 2 millimeters, 3½ millimeters, 5 millimeters, and 7 millimeters; one hydraulic classifier, having two sections; and three double jig-machines, each having eight sieves, four on each side of the box, and forming two complete four-sieved jigs. The sieves on two of these double jig-machines, used for 2 millimeters, 3½ millimeters, 5 millimeters, and 7¼ millimeters, are 18 inches by 32 inches. The sieves for treatment of fine stuff are 16 inches by 32 inches. The sieve proper consists of a wooden net-shaped frame covered with No. 10 and No. 15 copper wire clothing. The jig-machine for 2 millimeters, 3½ millimeters, 5 millimeters, and 7¼ millimeters has side discharge (Rittinger) 4 inches square, and bridge regulated by a movable slide. The jigs for fine stuff, 1 and ¼ millimeters, have bottom discharge. The jig-machine for the coarser stuff furnishing the most mixed stuff for recrushing is placed so high that it can spout this stuff to the crushing-rollers.

The motive power consists of a direct line, double balance crank, horizontal engine with cylinders 11 inches in diameter and 12-inch stroke. A 35 horse-power boiler is provided to furnish steam for the engine, and a No. 5 Cameron pump lifting water from the creek to a tank near the concentrator, to supply the boiler and machinery with the necessary water.



The raw ore is dumped on a platform in front of the Blake breaker, by which it is broken in pieces of one inch and less, spouted to the crushing-rollers, and crushed sufficiently. From the crushing-rollers it drops into the elevator, and is lifted to the revolving sizing-screen. The screen divides the crushed stuff into 2, 3½, 5, and 7¼ millimeters. The stuff larger than 7¼ millimeters is returned by a spout to the crushing-rollers, and the 2 millimeters and less is subdivided by the hydraulic classifier into three grades, 2, 1, ¼ millimeters. The 5 and 7¼ millimeters is spouted from the screen to the double jig-machine near the crushing-rollers; the 2 and 3½ millimeters to the one opposite; and the fine stuff, 1 and ¼ millimeters, to the jig on the end part of the building. Each of these six sizes has for its separation four sieves, having a jigging surface of 16 square feet.

The first sieve of the jig-machine discharges very clean galena; the second sieve, galena and zinc-blende mixed; the third sieve, clean zinc ore; the fourth sieve, zinc ore and rock; and the overflow is clean rock. The galena drops from the discharge into boxes; the clean zinc ore from both sides of the jig is spouted to small cars on the end of jigs; and the tailings are spouted to the outside of the building.

The capacity of these works is sixty-five tons per twenty-four hours. The force to run it is one hand feeding the Blake breaker, one hand attending to the jigs, and one hand for removing the clean product to the outside—a total of three hands for one shift. The cost of all the machinery complete, including engine and boiler, was only $5200.

Front Elevation.

Side Elevation.

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. We do not hold ourselves responsible for the opinions of our correspondents.]

Mr. Arents and the Stetefeldt Furnace.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Mr. A. Arents, of Alameda, Cal., has written a report upon the metallurgical treatment of the ores from the Mount Cory mine, Esmeralda County, Nev., which contains such valuable generalizations as to certain combinations of machinery and processes that they should become generally known. The crushing of the ore is to be done by Krom's steel rolls; and for extracting the silver, lixiviation with hyposulphite solution will be adopted. As the most important point to be settled, there remained the selection of the roasting-furnace. Let us see how Mr. Arents disposes of this question. He says:

"For roasting in a Stetefeldt furnace, and subsequent amalgamation, or amalgamation in any case, finely-divided pulp is required; while for purposes of leaching, a coarse material is just as good, and even preferable, for which reason stamps, Stetefeldt furnace, and amalgamating pans should go together, and rolls, cylindrical roasting-furnaces, and leaching-tubs also."

After speaking of the cylinder furnaces at the Geddes & Bertrand mill, Nevada, he says:

"A Stetefeldt furnace of the same capacity these four furnaces possess will use about 5 cords of wood, 5 per cent of salt, and 3 men in 8-hour shifts in the twenty-four hours, the Stetefeldt furnace not requiring any power to drive it, except the elevator and screen, which is very little compared with the power to drive these four furnaces, each of which requires from 4 to 6 horse-power all the time. All these facts speak in favor of the Stetefeldt furnace. But, at the same time, the Stetefeldt furnace requires finely-divided pulp, and to obtain it stamps are necessary, while stamps are certainly more expensive in every way than rolls; and, after roasting such fine pulp, amalgamation must follow, which again is in every respect more expensive than leaching."

These sentences seem to possess the ring of good coin, and may be taken as good law even by professional metallurgists, who have a limited experience only in this direction. I am myself a strong advocate of rolls versus stamps, and put my opinion in print before the success of Krom's rolls was established at the Geddes & Bertrand mill. I am also very enthusiastic about lixiviation, and have advised its introduction in the new Ontario mill in place of amalgamation. The results of the remarkable experiments which Mr. E. H. Russell has carried out at the Ontario mill with his new lixiviation process will be published shortly by myself.

So far, the conclusions of Mr. Arents have my earnest support. When, however, he proceeds to wipe the Stetefeldt furnace out of existence with a stroke of his pen, it is only fair that I should be granted a hearing because the good coin which he offers may be, after all, nothing but counterfeit.

Mr. Arents has made quite a reputation as a smelter, and he is well known as the inventor of the so-called siphon-tap for lead furnaces. His milling experience has been confined to the running of a tailings-mill in Dayton, Nev. With the Stetefeldt furnace he has had no experience whatever, and does not know what it can do, or what it can not do. In such a case, a man is easily misled, if he allows his fancy to formulate general laws.

Now, what are the facts in the case? A full discussion of this question would require more space than is at my disposal, and I can consider only the principal points.

The fineness to which an ore has to be pulverized for a complete roasting, preparatory to amalgamation or lixiviation, depends principally on the manner in which the silver-bearing minerals occur in the gangue. If the minerals are finely disseminated in a hard quartz, crushing as fine as No. 60 screen may be necessary. For ores of granular structure, much coarser screens can be successfully used. The limit in each case must be found by experiment. For amalgamation, this limit is fixed by the settler. The settler will not operate with coarser material than is produced by crushing in a battery through No. 30 screen. In order to convey a better idea of what this really means, I will state that if pulp crushed through No. 30 is sifted by hand through a No. 40 screen, only from 8 to 10 per cent of the ore does not pass this screen. At the Ontario, I had some ore crushed through No. 20 screens. Of this pulp, 13·8 per cent remained on a No. 40 screen. In this case, there was a marked difference between the value of the coarse and fine portions of the ore, the latter assaying 80 ounces, and the former only 30·2 ounces in silver per ton. At the Lexington mill, Butte, Montana, the difference between the fine and coarse portions was by no means so marked. In former times, No. 80 and No. 60 screens were used in dry-crushing silver mills. The wrong idea prevailed, that the results of amalgamation would be thereby improved. This idea was an inheritance from raw amalgamation, where the ore is finely ground in the pan. It was also an inheritance from the Freiberg barrel amalgamation, where the roasted ore was bolted. In this case, the bolting was done to get a pulp of uniform consistency in the barrel. The amount of water used in barrel amalgamation is hardly sufficient to bring all the soluble salts of the charge into solution. Hence any lumps in the roasted ore would not soften, and their silver remain unextracted. This is also the case, to a certain extent, in pan amalgamation. I have drawn attention to this fact in my article on the Lexington mill, which explains why chloride of silver is found in tailings.

The low capacity of the battery with fine screens stimulated to try coarser crushing, and No. 40 screens came into general use. For a long time, nobody dared to go farther. Finally No. 30 was given a trial with good results, and is now generally adopted. All attempts to go still farther have failed, on account of the impossibility of working heavy sands out of the settlers without losing quicksilver. Only recently a No. 26 screen was used at the Ontario, but had to be abandoned for the reasons stated above.

While there exists a mechanical limit in the coarseness of crushing for amalgamation, there exists none if lixiviation is used. Here it simply becomes a question how coarse can the crushing be done to get a perfect roasting, because those particles of mineral which have been reached by the roasting can, undoubtedly, also be reached by the solutions used for the extraction of the silver. If we closely analyze the two rules of Mr. Arents, and the explanations accompanying them, by which metallurgists are to be guided in the future, we have the following propositions: 1st. The Krom rolls can not produce pulp the principal percentage of which will pass through a No. 40 screen. Mr. Arents excludes the combination of rolls and amalgamation, and distinctly states that to obtain such pulp stamps only can be used. 2d. Finely-divided pulp is essential for amalgamation. This statement is somewhat loose, since Mr. Arents does not give the size of screen. But it is evident he meant that for amalgamation a large percentage of the ore should be in that fine condition which approaches dust, and is produced largely by stamps, and much less by rolls. 3d. Ore crushed by stamps and roasted in a Stetefeldt furnace must be amalgamated, and can not be worked by lixiviation. 4th. The Stetefeldt furnace can not roast ore which is crushed by rolls, since it can treat finely-divided pulp only. This statement is also loose, but, most likely, intended to convey the same meaning as in the second proposition.

Let us examine these propositions in detail.

1st. Regarding the first one, I beg to refer to a correspondence from Mr. Krom, who knows best what his rolls can do:

C. A. STETEFELDT, M.E.:

DEAR SIR: In answer to your inquiry in relation to the capacity of my steel rollers for producing pulp which will pass through a No. 40 wire screen, or finer, I have to say that there is no more difficulty in crushing fine with rollers than with stamps. The difference is, however, in favor of rollers for producing fine pulp. The fineness to which the ore is crushed in either case limits the capacity. For example, we have demonstrated that two sets of 26-inch steel rollers are equal to about 50 stamps, say of 750 pounds each, whether the ore is crushed fine or coarse. The amount of fine dust produced by rollers is not so great as when the ore is crushed by stamps. At the Austin mill, I found that crushing with rollers through a No. 16 mesh screen there was produced 16 per cent of fine pulp, which passed through a No. 100 screen. One half of this went into the dust-chamber as floating dust. Yours very truly, S. R. KROM.

2d. If Mr. Arents is of the opinion that finely-divided pulp is essential, or even beneficial for amalgamation of roasted ores, he is very much mistaken. The fine dust which is drawn from the dust-chambers of a Stetefeldt furnace, if amalgamated by itself, gives results far below its chlorination. There is a good opportunity at the Ontario mill to observe this fact. The dust escaping from the battery is collected in a long flue, which can only be cleaned when the battery stops. As many as 30 tons of dust accumulate in this way, and have to be roasted by themselves when the mill is to be shut down. Although well chloridized, this dust yields in amalgamation only from 75 to 80 per cent of its silver, the regular mill work being from 89 to 92 per cent. The crushing at the Ontario was formerly done through No. 40 screens. A change to No. 30 produced no detrimental effect. Recently the No. 30 screens were replaced by No. 26 screens. Mr. Russell has averaged the mill work for two weeks prior to the change, during the change, and for two weeks after it, with the following results:

	Furnace No. 1.	Furnace No. 2.
Using No. 30 screen.....	89·8 per cent.	89 7 per cent.
" No. 26 "	90·0 "	91·1 "
" No. 30 "	90·4 "	90·2 "

If these results prove any thing, they prove that coarse crushing is rather beneficial than injurious to amalgamation. Most decidedly, it is not essential. At the Lexington, the ore coming from the battery was passed through a Krom revolving screen with No. 40 wire-cloth, and about 10 per cent of coarse material was returned to the battery for recrushing. It was done as an experiment, and also to relieve the settlers. The returning of the coarse material to the battery proved to be inconvenient, disturbing the action of the self-feeders, and Mr. Wartenweiler provided the Krom screen with No. 30 wire-cloth. No increase in the value of the tailings was observed, and the amalgamation of the silver has averaged, from December 1st to April 1st, 90·6 per cent.

At the Panamint mill, I tried crushing through No. 20 screen, without lowering the results of amalgamation, but could not continue to use it on account of settler work.

3d. That ore crushed by stamps and ore roasted in a Stetefeldt furnace can not be worked by lixiviation is a most remarkable statement. Since Mr. Arents seems to be satisfied that ore crushed by stamps can be well roasted in a Stetefeldt furnace provided the pulp is finely divided, he refers, no doubt, to the mechanical difficulties of lixiviation merely. Here again he imagines that he has to deal, principally, with impalpable dust, which would prevent filtering of the solutions. Very likely he is also entirely ignorant of the fact that nearly all the dry-crushing silver mills now use No. 30 screens on the battery, as we have stated above. But we have an array of facts which flatly contradict his assumption. Mr. Russell's lixiviation experiments at the Ontario mill, which have been conducted on a working scale with charges of 2 tons in one tank, have met with no mechanical difficulties whatsoever. The solutions pass freely through a charge 30 inches in depth. Forty tons of Ontario ore extracted by lixiviation yielded 92·6 per cent of the silver, when amalgamation, at the time these experiments were made, extracted only 90·2 per cent. It will be of importance to state that the character of Ontario ore is by no means very favorable for the mechanical part of lixiviation, since it contains about 25 per cent of clay.

Mr. Arents should also be aware of the fact that O. Hoffman has successfully leached the ores from the Silver King mine in Arizona, and that lixiviation is in use at the Barranca mine and others in Sonora, Mexico. In both cases, the ore is crushed by stamps. In the first case, the roasting was accomplished in cylinder furnaces; in the second case, in reverberatory furnaces.

4th. We now come to the most important proposition, namely, that the Stetefeldt furnace can not roast ore which is crushed by rolls, since it requires finely-divided pulp.

We have stated before that for a certain ore there exists a limit of coarseness in crushing in order to obtain a good roasting. This limit, in

Digitized by Google

particular cases, has not been reached with the Stetefeldt furnace, because, wherever this furnace has so far been used, amalgamation follows the roasting. We have also stated that the limit is fixed by the capacity of the settler to deal with coarse material. Neither are there facts extant as to this limit, if the roasting is done by furnaces which roast the ore in charges, and not by a continuous process. Taking it for granted that this limit is sooner reached by the Stetefeldt furnace than with the reverberatory or cylinder-furnace, it becomes a question of economy to which furnace preference should be given. Now of the different operations through which the ore has to pass, the crushing is the least costly, and the roasting the most expensive.

It is also evident that, if we approach the limit of crushing for periodically working furnaces, the charge will have to be kept a longer time in the furnace to effect a complete roasting of the coarser particles. If this was not the case, why, for instance, would it be necessary, at Mansfeld, to pulverize the copper matte so fine for the Ziervogel process that it will pass a No. 32 wire screen? Here, too, leaching follows the roasting. Hence, with coarser crushing, we need a more extensive furnace plant, and augment the cost of roasting. Mr. Arents himself puts considerable stress on the economical working of the Stetefeldt furnace as compared with the cylindrical furnaces. After all, the two limits can not be very far apart, and a slight increase in the cost of crushing and a considerable saving in the expense of roasting must be considered as the only true economy.

Old statistics on the working of the Stetefeldt furnace have created the impression that the dust is better chloridized than coarser portions of the ore. Those statistics came from mills where the roasted ore is immediately cooled after discharging, and not "banked up" and left in red-hot state for twelve hours on the cooling-floor, as done in the Ontario and Lexington mills. For some ores, this treatment is not essential, and, in fact, the older mills had no facilities for doing it. Other ores are so materially benefited thereby that differences in chlorination as high as 45 per cent may occur if chlorination tests are made, taken immediately after discharging, or after the ore has been left for twelve hours on the cooling-floor. The dust-chambers are not discharged frequently, and the last ones may be left undisturbed for a week. Consequently, the ore in these chambers has already gone through the "banking-up" process by the time it is discharged. If, in the cases to which reference is made above, the ore from the shaft had been left for twelve hours on the cooling-floor, and then sampled, the chlorination would have been several per cent higher, and above that of the dust.

That coarser crushing does not deteriorate the work done by the Stetefeldt furnace is partly shown in answering the second proposition of Mr. Arents. But some more facts will be adduced here. When the experiment of crushing through No. 26 screen was made at the Ontario, the chlorination tests with Mr. Russell's improved lixiviation process gave the following results:

	Furnace No. 1.	Furnace No. 2.
Using No. 30 screen	92·2 per cent.	92·4 per cent.
" No. 26 "	92·8 "	93.0 "
" No. 30 "	92·3 "	92·5 "

In reference to these experiments, Mr. Russell writes to me: "I think the Stetefeldt furnace would chloridize as well ore crushed with No. 20 screen as with No. 30 screen on the battery."

Mr. Russell also made the following experiment. A number of cars of roasted ore drawn from the shaft, return-flue, and dust-chambers of the Stetefeldt furnace were sampled immediately after discharging, and subjected to Russell's lixiviation test:

	Silver extracted.
Roasted ore from shaft	93·2 per cent.
" " return-flue	91·8 "
" " dust-chambers	91·4 "

Further comment is unnecessary.

The supposition that the Stetefeldt furnace requires finely-divided pulp is entirely refuted.

If Mr. Arents wants any of my statements verified, he will please address the proper parties to whom I refer. He also will oblige me by a reply.

C. A. STETEFELDT.

24 CLIFF STREET, NEW YORK CITY.

OFFICIAL STATEMENTS AND REPORTS.

THE RAY COPPER COMPANY, MINERAL CREEK, ARIZONA.

The Ray Copper Company, of which George H. Sargent, of New York, is president, and Louis Zeckendorf, secretary and treasurer, is a company recently incorporated under the laws of the State of New York, with a capital of $5,000,000 divided into 500,000 $10 shares, of which 125,000 shares have been reserved to provide a working fund. Under date of December 20th, 1882, Col. John M. Haskell reports on the property, which is located in the Mineral Creek District, Pinal County, Arizona, and embraces seventeen mining claims, a furnace rated at 30 tons, water-right, etc. There are two groups of mines, the first the Ray group, on one vein, reported to be of great width and carrying large bodies of rich copper ores. Mr. Haskell figures out over 2000 tons of ingot copper in one block, 150 feet long and 50 feet in depth. Some development-work has been done on it. The ore carries principally native copper, and it is proposed to crush and wash it. The second group of mines, including the Bilk, Scorpion, and Munroe, are narrow veins, but little developed, carrying carbonate smelting ores. They and a number of prospects are estimated to have 3000 tons of 20 per cent ore in sight, and the work of putting them through the smelters is to be begun at once.

AN OLD ENGINEER DEAD.—On the 11th of June, Calvin Briggs, who fired the first coal-burning engine, the Phœnix, on its first trip over the Long Island Railroad, and who is said to have run an engine more miles without repairs than any other engineer, died suddenly at Greenbush. The original cause of his death was an injury received in a steamboat explosion thirteen years ago.

THE CLEVELAND MEETING OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

The arrival of increasing numbers of mechanical engineers during Monday and Tuesday made the appearance of the blue badge of membership more and more frequent at the head-quarters of the society, the Forest City House; and at the opening session of the society, the rooms of the Vocal Society at the City Hall were completely filled, fully one hundred ladies and gentlemen being present.

Mr. J. F. Holloway, Chairman of the Local Committee, introduced Mayor Farley, who, in behalf of the citizens of Cleveland, welcomed the society. Mr. E. D. Leavitt, Jr., of Cambridgeport, Mass., President of the Society, made a brief reply, in which he dwelt upon the beauty of the city, and then called upon Mr. J. F. Holloway, of Cleveland, President of the Cuyahoga Steam Furnace Company, for his paper on

THE MARINE ENGINES ON THE LAKES, AND A DEVICE FOR GETTING THEM OFF THE DEAD-CENTERS,

in which he sketched the history of the development of the marine engines of the lakes. The carrying capacity of the vessels has been largely increased, and the peculiarities of the navigation of the lakes have made it necessary to obtain this mainly by adding to their length and beam, rather than by increasing their depth of hold. Since the strength of a hull is largely dependent upon the depth of its sides, and since the overhead arches, formerly used, have been found of late years to interfere with loading iron ore and lumber, the difficulty now is to build a hull that shall be strong enough to carry, in addition to its own cargo, the power required for its own propulsion, as well as the power required to tow one or two vessels of the same tonnage behind it. One of the results of putting such powerful machinery into hulls of this description is, that the hull, being long and comparatively shallow, lacks vertical stiffness. It readily responds to the pulsations of the engine, until, at certain speeds, where the number of strokes comes into unison with what might be termed the time of vibration of the hull, due to its weakness, the shaking becomes a very serious matter. While this is true of an engine having a single crank, the use of engines having double cranks placed at right angles does not in the least help the matter; for not only are cranks so placed much more difficult to balance, but they have, in addition to the up-and-down motion, another motion which may be called an *athwartship* motion. When the crank-pins of such an engine are both on one side of the main shaft, they produce a severe side-thrust upon the main journal-bearing, opposite them, which tends to push it sidewise. This side strain, on the return-stroke of the piston, is of course transferred to the other side of the journal-box, and thus these alternating side-thrusts, added to and merging into the up-and-down motions, combine and form a sinuous motion much more destructive to the hull than the simple up-and-down motion first referred to. Of course, these difficulties are increased when the engines are to any extent unbalanced, experience having shown that, the better all engines are balanced, the less will be their influence upon the hull. The first successful attempt to overcome this vibratory action of the engine upon the hull was made in the construction of the steamship Amazon, which was built in the year 1873. The hull of this vessel was in some respects peculiar: it was 240 feet long, 40 feet beam, and 20 feet depth of hold. She was propelled by twin screws, and had two stern-posts, and was built without overhead arches. Each wheel was driven by a pair of fore-and-aft compound engines; but the cranks, instead of being placed, as usual, at right angles with each other, were placed so as to bring the crank-pins directly opposite each other. These engines made, ordinarily, 75 revolutions per minute, and so well was the labor divided between the two cylinders, and so carefully had the reciprocating parts of the engine been balanced, that the main shaft, instead of being first pounded down on the bottom of the journal and then against its cap, seemed to be almost suspended in the air. The result was, that there were no vibratory motions to be transferred to the hull, and it was almost impossible to tell, when standing on the bow of the boat, whether the engines were in motion or not. As a better evidence still of the value of this arrangement of the crank-shafts of a marine engine, there is an instance of a large propeller built recently, which had a pair of fore-and-aft compound engines, coupled to the main shaft in the usual way by cranks placed at right angles with each other. While the construction of the hull of this propeller differed in no way, either as to its shape or strength, from boats as usually built, it was so severely shaken by the machinery during the first season it was in commission, that it was very evident to the owner as well as the crew that it could not long endure such usage. At the close of navigation, the cranks upon the main shaft were so changed as to bring the crank-pins directly opposite to each other, and the result was, that the hull no longer suffered from any motion of the engine.

Vessels heavily laden are now obliged to move slowly and with great caution while entering or leaving port, and the frequency with which the engines are made to stop, start, back, or go ahead, renders them quite liable to "catch on the center." Owing to the crowded condition of the ports, and the numerous bridges to be passed, if an engine is thus, even for a brief time, disabled, there is great danger lest the vessel shall do or receive serious damage before the engine can be started "off its center," in the usual way—the usual way being to hunt up an assistant or a fireman and send him below slowly to pinch over the crank-wheel, with a pinch-bar—an operation not only slow, but also dangerous. Mr. Holloway describes the device which he has successfully employed for starting the engine off its center as follows:

It consists of a short-stroke steam cylinder, located in the hold of the vessel, and alongside of the propeller shaft. I place it at the point where the in-board and out-board shafts are coupled together, as the rim of the coupling is very convenient for carrying a portion of the machinery. I place on the coupling-flange or on the shaft a wheel having on its face a series of V friction-grooves. Opposite to this friction-wheel, I place either a short segment of a wheel, or a short straight block of iron, which has upon its face a series of V friction-grooves corresponding to those on the wheel. This block or segment, as may be most convenient to be used, is connected directly with the piston-rod of the short-stroke steam cylinder; and it is also so arranged that it may be made to move toward

Digitized by Google

the friction-wheel, and to come in close contact with it, by means of an eccentric journal, or a similar device.

Now, if in working the main engine forward or back, it becomes caught upon either the upper or lower center, the valve-gear of the engine may be set for turning the engine in the direction wanted, and the throttle-valve may be opened so as to admit steam on the piston if desired. Now, if the block or segment of the starting engine be brought in close contact with the friction-wheel on the propeller shaft, and steam then be admitted to the piston of the starting engine, the friction-wheel and the shaft to which it is attached will be turned a distance equal to the length of the segment or the block. This distance is regulated by the length of stroke of the cylinder of the starting engine, and will be just enough to throw the crank "off the center."

The main engine will move off at once, having already had its valve gear placed in position, with the throttle-valve open; while the starting engine has pulled or pushed the segment or block out of gear with the friction-wheel, and of course out of the way, without any further attention from the engineer. The handles for bringing the block or segment into gear with the friction-wheel, as well as the handle for admitting steam to either side of the piston of the starting engine, will both be placed conveniently near to where the engineer stands while working the main engines. He is not obliged to leave his place to work the starting engine.

The starting engine is designed to work either way, and to turn the engine off either center. If, when it is required for use, the piston should happen to be at the wrong end of the cylinder, the engineer will move the block or segment back from contact with the friction-wheel, will make one stroke of the piston without touching the wheel, and will then move the segment or block back in contact again, when the starting engine will be ready to turn the propeller shaft in the direction wanted. This is done with but a very slight loss of time, and without any necessity for calling upon any one for assistance.

The next paper was by Mr. Howell Green, of Jeanesville, Pa., on

THE HISTORY AND DEVELOPMENT OF THE WINDING AND PUMPING MACHINERY OF THE ANTHRACITE COAL REGIONS.

The anthracite coal-beds of Pennsylvania (some 15 in number)—classified by the color of the ash—may be divided into four groups. The uppermost group is red ash; the second, gray ash; the third, white ash; and the fourth, or lowest group, is, again red ash. This color of the ashes might seem more of a chemical than a mechanical question; but as it is a tolerably sure criterion of the condition of the water in the mine, as well as of the burning properties of the coal, it was early noticed.

These beds of coal lie at every possible inclination to the horizon, dipping under the surface over 2000 feet (say 1000 feet below the level of the sea), and running up mountains hundreds of feet above the beds of adjacent streams.

The first coal was mined where it was most easily got at, so that in the earlier days of the trade (which commenced about 1820), only drifts or tunnels above water-level, and strippings near the surface, were used to get the coal.

Soon the requirements of the market made it necessary to go into the depths of the earth for coal, and means had to be provided to hoist the same, and to keep the mine clear of water.

The soil in the coal regions is poor; and before mining began, population was sparse, the few inhabitants combining hunting, fishing, farming, and lumbering in about equal proportions for a livelihood.

On the influx of strangers, who thronged to the newly-opened mines, among others there came miners and engineers from England, Scotland, Wales, and Germany, who had seen mining machinery and appliances at home; and here in the new world they constructed engines and pumps. Native ingenuity and the absolute necessities of the situation prompted men to plan and build the contrivances to win the coal. Money and enthusiasm lent their powerful aid, and the ever-increasing sum of human knowledge has made it possible to show, in the last number of the series of mining plants, very handsome examples of the mechanical engineering of the anthracite coal regions. The progress is shown in that series from first to last. Some of the early members are yet standing, in obedience to the old law of the survival of the fittest; while many of them kindly (though sometimes unkindly) have been consigned to the cupola and heating furnace, where have been transmuted so many darling creations.

Very early in the progress of mining below water-level, it was seen that means had to be provided to hoist from 300 to 400 feet at one lift, so as to get space for breasts, to work the coal profitably; and the quantity of water to be raised was found to run into hundreds of gallons per minute. From the first, both slopes and shafts were used. The mine-cars in the anthracite regions have always been large, starting in the early days at about 40 cubic feet capacity, and standing now at about 96 feet. The wheels of the cars have been from 12 to 20 inches diameter; 18 inches is now most generally used. The axles have been from 2 to 2¾ inches diameter. The gauge of the mine railroads varies from 30 inches to 48 inches; in a few cases, it is 4 feet 8½ inches. At first, chains were used for hoisting, and some of the early shafts had hemp ropes. Flat chains, or rather, three chains side by side, with alternate large and small links, and with blocks of wood through the large link, were tried. These flat chains were wound on flanged spools like a ribbon. Iron and steel bands were used, but the conclusion of the greatest number now is to use iron-wire round ropes. Not that iron-wire ropes are better than steel-wire ropes; but questions of endurance, cost, etc., in relation to wear and weight and work in acid water, have rather been against steel-wire ropes. In a shaft, no rope rollers are used, but on a slope—particularly one with varying pitches—the question of a roller to protect the rope is most important. While it has been a vexed question, yet after trials of hundreds of forms and many kinds of material, it seems to be considered that a hardwood roller about eight inches diameter, truly turned, and kept clean and clear, is the best for ordinary strains. It was soon found out, in using wire ropes, that the life of the rope was much lengthened by making the drums and sheaves of large diameter; the rope must spring around the drums and sheaves, and spring back, and not receive a permanent set.

The first steam-engines used for hoisting anthracite coal and pumping the water (and at first they combined both duties) were single high-pressure engines, with flat bed-plates bolted on wood frames. The steam cylinder would be perhaps 18 inches diameter, with 6-foot stroke. A cast-iron crank-shaft, with perhaps a 10-inch journal, carried the heavy fly-wheel. On the crank-shaft, there was a pinion 30 inches diameter, of 8 inches pitch and 12 inches face, which geared into a drum-wheel 60 inches diameter, which was just above the pinion. Just under the pinion, was the pumping-wheel, 8 feet diameter; this pumping-wheel had holes in it to receive a pin for working the pump. The drum-shaft was of cast-iron, with perhaps an 8-inch journal; its body, as that of most all other shafts then, was octagonal, and the drum-wheel spiders and almost every thing else were staked and keyed on by the methods of the old millwrights. The drum was from 5 to 8 feet diameter, and about 11 feet long, and was formed of hardwood laggings bolted on spiders. To wind a car 400 feet with a 5-foot drum, the engine would have to make about 48 revolutions, which it was made to do in about one minute. The pumping-shaft was also of cast-iron, with perhaps 11-inch journals; and the drum-shaft was lifted in and out of gear by a strong wooden lever, one of the pillow-blocks being hinged for that purpose. The pump was, of course, near the bottom of the mine, perhaps 400 feet away. It was a lifting-pump, 16-inches bore, 7-foot stroke, fitted with a bucket faced with sole-leather, the rod of which went through a stuffing-box in a goose-neck or turn-piece. Up the slope or shaft went a wooden rod, 8 inches square, carried on flanged rollers. The rod was spliced with plates 4 inches by five eighths of an inch by 10 feet, and on top of the slope or shaft were one or more rocking bobs, provided with great balance-boxes.

The rods connecting the balance-bobs to the wheel were 8 inches by 16 inches, and were provided with suitable straps, etc.

The valve-gear of this engine consisted of two eccentrics and rods with hooks on the ends, which the engine-man lifted in and out of gear with his feet, thus leaving his hands free for full control of the slide-valve, which he operated with a long bar. He regulated the quantity of steam for the engine by a throttle of the stovepipe-damper pattern. Thirty years ago, such a pumping and hoisting-engine was considered first-class, and many of the old fellows are yet at work.

Such an apparatus was subject to many mishaps. With a heavy fly-wheel whirling around, and the slide-valve at the will of the engine-man, unnecessary strain could be easily thrown against the engine, and broken cranks and shafts were often the consequence. Also, if in lifting the drum out of gear, it was not securely scotched, the unbalanced end of the chain would fly down the slope or shaft. When it was necessary to connect or disconnect the pump-rods, the rocking bobs had to be securely blocked, and sometimes the assistant forgot to take out the last block—and then trouble came.

This state of affairs was much improved by putting up another engine, so that one engine could pump, and the other one could hoist. Next it was discovered that two engines could be attached to the same shaft, at right angles to each other, so that no fly-wheel would be wanted. Yet on some of the first pairs so built, small fly-wheels were put on—probably to verify Darwin's theory of gradual development. The first of these double engines had two eccentric hooks to each engine, making four in all, which the engine-man had to lift with levers now he had two engines to handle, and it took a lively man to do it; but since there was little or no fly-wheel, no great danger was incurred. The engine-man, therefore, hooked one engine in and started the load with the free engine. These double engines with four hooks did very well. Next, links for valves were introduced, and they are now generally used.

It was found that hoisting and pumping-engines in which cog-wheels were used were subject to noise and break-downs; and as the miners went deeper, it was found that drums keyed immediately on the crank-shaft of a double engine did the best. This change, of course, involved larger steam cylinders, and in the place of wood-faced drums cast-iron ones were made, which soon led to the use of spiral grooves to keep the ropes from chafing. Still further, these drums were made conical, so that when the heavy load was to be started, the small end of the cone did the pulling, while the empty car (and cage, if in a shaft) pulled by the large end of the cone on the other side. This arrangement is the best yet tried, and so the hoisting-engines stand to-day. These are strongly-built double engines on strong stone foundations, with steam cylinders from 20 to 40 inches diameter and stroke from 4 to 6 feet. There are heavy wrought-iron shafts, spiral-grooved cast-iron conical drums, steam-brakes and steam reversing gear, with appliances to prevent over-winding, with safety-catches and detaching gear; and, barring waste of steam, the world can show no better hoisting-engines than are in the anthracite coal regions of Pennsylvania.

To a mine below water-level, the pump, or other appliance to raise water, is of first importance. When man enters nature's great store-houses in search of wealth, he finds that water is ever ready to dispute his supremacy. Sometimes it is the constant stream, only varying with the season; often there are great quantities stored in the crevices of the rocks. In parts of the anthracite coal regions, the fact has been shown that the first 100 yards down the vein has the most water; the next 100 yards has less; and after that, the vein is often perfectly dry. Perhaps the most discouraging situation for a mechanical engineer to be called to in the anthracite coal regions is to have to provide the remedy for an old drowning mine, where the vein is large, the pitch steep, the top bad, the mine full of fire-damp, the timbers old and rotten, and the water so full of acid that it will eat up a shovel in a night, with the air so close that one can hardly breathe. On these occasions, darkness and danger are our companions, and great expense and long delay are our inevitable followers.

The first mining-pumps used were of the Cornish pattern—the old drawing lift with an iron bucket faced with leather. This leather was held in place by a wrought-iron or brass ring which nearly fitted the working barrel, and was driven full of wooden pegs. If the working barrel was made of hard iron, and the length of the rod nicely adjusted so that the leather would come slightly above the bore in the up-stroke, and if the water was clean and not acid, and the lift not too heavy—then, this is still the best mining pump ever made. The red-ash veins were the first ones worked below water-level, and the water in red-ash mines will not, as a rule, eat up iron; but when slopes and shafts had to be sunk on the white-ash veins, there the lifting-pumps would not do. The sulphuric acid in the water ate them up. Some brass

Digitized by Google

working barrels and brass rods were tried, but they were expensive and short-lived. Open-topped force-pumps were made, hoping that they could be lubricated and made to stand; but the general conclusion arrived at, about the year 1848, was, that plunger pumps must be tried. Since that time, they have been generally used, and the reason of their longer life is, that plungers can be lubricated and the corroding action of the acid water lessened. As the first lifting-pumps were worked by rods running up to the engine, quite a change in balance-boxes occurred when lifting-pumps were changed to plungers, and about this time quite a number of double-acting pumps were put in. These pumps, of course, discharged water at each pass of the piston, and had four valves instead of two. About the years 1854 or 1855, the Bull engine and pump were introduced. These did away with cog-wheels for pumping, as the pump-rods were fastened to the piston-rod of the steam-engine. No fly-wheel or crank was necessary on these engines, since the cylinder was made large enough to lift the rods, which were made heavy enough to force up the water on their downward stroke.

These engines and pumps have been a real success. They had to be very strong, from the nature of the case. The valve-gear is beautiful. It is the result of one hundred years' experience in Cornwall, whence the idea came. The engine-man has to be a man of good judgment, as he deals with very heavy weights. Yet, as regards consumption of steam, the two-valved engine of the anthracite coal region compares very unfavorably with the three-valved Bull engines of Cornwall.

About the year 1860, steam-pumps began to be used in the coal mines; the great departure being in bringing the engine and pump together; and from the unfortunate nature of the case, the engine had to be taken down in the mine from 500 to 1000 feet from the boilers. Here commenced another trouble, which is the great loss of power of the steam so conveyed.

Strange as it may seem, the old war between acid water and pistons and rods had to be fought over again, and the acid water came out ahead with steam-pumps, just as it did with lifting-pumps.

This paper must be too short to go over all the questions of steam-pumps, with their valve movements—positive, isochronal, and steam-moved—of pumps alternate and reciprocating, with bronze linings, rods, and valves; with roomy valve-chambers and easily changed seatings, etc., with air-chambers and air-lodgments; together with questions of relative size, speed, and portability. Yet I must take time to say, that to pump acid water, a plunger seems the best, because it can be protected by grease (in cold water), and the action of a piston on the lining of a pump will even hasten the corroding action of the acid water; that steam carried from 500 to 1000 feet, in pipes ever so well covered, will lose much of its power; that ordinary high-pressure steam-engines, using such steam and making no use of the principles of expansion, are great wasters of steam; that centrifugal pumps, even with short lifts, will hardly do for acid water; that the introduction of steam into vessels just emptied of cold water seems to return to the days before James Watt; that the ponderous engines of Cornwall, or the splendid examples lately set up at our American water-works, are too costly for the ever-changing locations incident to anthracite coal mining; and that while to men who daily see hundreds of tons of good culm thrown away small savings of steam seem foolishness, yet in view of the great fact that in the best steam-pumps in the coal regions the fuel used is four times as much as it might be, there seems room for improvement on that score. As the pumps now stand in the anthracite coal region, those which use the least fuel are the old plungers, worked by engines on the surface, using cog-wheels and pinions. Next in point of economy are the Bull pumps. Then follow various kinds of steam-pumps—good, bad, and indifferent. None uses the principle of expansion to a very great degree, and the duty done by 100 pounds of coal may be stated at from 10,000,000 to 20,000,000 pounds of water raised one foot high.

The pumping of the water of the anthracite mines is an ever-increasing trouble. The mine widens, the outcrops fall in, and as the quantity of coal to be had decreases, the water increases. For this state of affairs, there is no help. Some colliers in the middle coal-field use, at certain seasons of the year, one hundred tons per day for pumping water, to raise 8,000,000 of gallons in twenty-four hours from a depth of four hundred feet. When wet seasons come on, the water in the mines gets more troublesome on account of acid which is extracted from the rubbish left in the mine. The water of the mines is not good for use for purposes of condensation, because, when heated to one hundred degrees, it acts on iron with increased force. Fresh water gets more and more scarce, and water is brought long distances by pipes, and often in cars, to supply the boilers; and in some districts, good artesian wells are bored. Here, however, another troubles comes in: if the holes go down too deep, the mountain limestone is reached, and lime is more troublesome than sulphuric acid. But by mixing the two together, under intelligent care, a good water is obtained.

And so the situation is. The question that to-day troubles the minds of many engineers in the coal regions is, How had we best build our mine pumps—shall we stick to the old method of a plain steam-pump, with no expansion or condensation, because it is so handy to put in and take out? So far as the pump alone is concerned, the answer seems, Yes; but when we see the long row of boilers, and immense piles of fuel for them, it calls attention to the other side of the question. If by this imperfect sketch, the writer shall have called the attention of this society to this difficult and important question, he will be satisfied.

The last paper of the session, which we print below, was that of Mr. George N. Comly, of Wilmington, Del., on

ECONOMY IN LUBRICATION OF MACHINERY.

In large manufacturing establishments, the sum of money paid annually for lubricants is surprisingly great, and, where oil is the lubricant, the quantity wasted is a very large percentage of the total amount purchased. Being convinced that such was the case, I endeavored to ascertain the actual quantity of lubricating material used in a given time on the various machines and in the various shops connected with the establishment at which I am engaged. The result was startling, and the investigation proved that one of the most extravagant users of oil was the vertical engine used for driving the principal part of the works used for machine-shop and bridge construction, etc. The engine was nominally 60 horse-power, with 16-inch cylinder and 18-inch stroke, with an 84-inch diameter pulley, making 106 revolutions per minute; but the indicator cards were evidence of the fact that frequently 83 horse-power were produced by the engine. Owing to the fact that the engine was overloaded, the crank-shaft bearings and crank-pin gave much trouble by heating, and occasionally it was necessary to stop the engine during working hours. The expense for lubricating oils on this engine during the month of May, 1882, was at the rate of 3·53 cents per hour of the time during which the engine was actually running. The oil used was cosmo-lubric No. 2, costing 65 cents per gallon, and the specific gravity of the oil was 26 Baumé. During June, the oil cost 3·91 cents per hour run, and the engine was running 120 hours per week, or on an average of 20 hours per day. About the 1st of July, I commenced using No. 10 lubricine-grease on the crank-shaft bearings *instead of oil*, and the result was, that the engine shaft-bearings worked much cooler, gave no more trouble, and the cost of lubricating material was reduced to 1·15 cents per hour run. The crank-pin at this time was still using oil, and continued so doing until October 9th, when I had a copper box attached to the stub-end of the connecting rod close to the crank-pin with a ¼-inch tube connecting the box with the crank-pin bearing, and No. 4 lubricine grease packed in it. No. 10 lubricine was also applied to the guides for the cross-head, the result being that the cost of lubrication was still further reduced to 0·78 of 1 cent per hour run, and the guides and pin worked much cooler than they did previously when oil was used. A mixture of palm-grease and bees-wax in proper proportions will compare favorably in efficiency with the lubricine-grease. I have also found mixtures of bees-wax and tallow or bees-wax and suet to work very well as lubricants for shafting. The relative proportions must, of course, be made to suit circumstances.

During the past eight months, the line-shafting has been running *without oil*, depending exclusively on the mixtures such as already described. The shafting is all provided with ball and socket hanger-boxes, and the top half of the box has two cups cast in it in which the grease is packed, each having a cast-iron cover fitting closely over it to keep out the dust. This cover is chained fast by a very light chain, to prevent it from being lost or knocked down by ladders, etc. The center oil-hole, where a self-oiler is usually placed, should be stopped up with a cork to keep out dust at that point, and the use of oil is not allowed on any of the shaft-bearings where the grease can be applied.

By the regulations already described, the cost of lubricants has been reduced 44·6 per cent in the cases noted above. Means have been provided for using the grease on nearly all of the engines running at the works and on several of the heavy machines, the result being a saving of lubricant and a cool running of the journals. It is better, when applying the grease, to make large holes in the caps of the bearings (perhaps 1½ or 1¼ inches diameter if allowable), and permit the grease to be packed directly on the journal surface. Where this can not be done, a funnel-shaped cup is attached to the oil-hole, in which is a copper rod, one end of which presses against the shaft while the other end passes through a spiral spring which is tightened to the required tension by a screwed cap. The cup is filled with the grease, and the rod passing through it melts the grease by the heat caused by the friction of the copper rod on the journal, the spring being tightened sufficiently to produce the necessary friction on the end of the rod. Plain copper boxes, however, are frequently preferable with lids to keep out the dust. A piece of copper rod run through the center of the box touches the shaft, and the hole between box and shaft is made much larger than the size of the rod of copper, so that the grease can be well pushed down on to the shaft.

A brief discussion followed in which it was argued that, as the friction in using grease was greater, the increased wear and tear would more than counterbalance the money in running expenses. After the acceptance of an invitation to inspect the working of a machine for making seamless pulp barrels, the members were introduced to the gentlemen of the Cleveland Civil Engineers' Club, with whom a few hours were spent in friendly intercourse and in the discussion of a collation.

THE SECOND SESSION.

After the transaction of some routine business, including a report by the tellers, announcing the election of a number of new members, a report by the treasurer and by the council, Mr. W. F. Durfee, of Bridgeport, Conn., was called upon to read his paper on Balancing Vertical Engines, in which he gave a detailed description of a vertical high-speed engine built by him as early as 1868 for the American Silver Steel Company, of Bridgeport, making frequent reference to drawings, without which it is not possible to follow his explanations. During a lively discussion which followed, and in which Messrs. Henning, Scott, Barnet le Van, Miller, Hamilton, Sweet, and others took an active part, an interchange of opinion and of experience was had concerning a number of points raised by the paper. The merits of vertical *versus* horizontal engines, for high speed particularly, brought out facts in regard to the piston speed now attained by some of the horizontal engines of the Porter-Allen and Buckeye class, it being reported that as high as 1200 feet had been attained without affecting the working of the engines.

This was followed by the reading of a long paper written by Mr. W. E. Ward, of Port Chester, N. Y., on

BETON IN CONJUNCTION WITH IRON AS A BUILDING MATERIAL.

Noting, as early as 1867, how great was the adhesion of cement to iron, Mr. Ward gradually, and through a long series of experiments, worked up the reciprocal value of béton in combination with iron, first in construction of beams designed for supporting the floors and roofs of houses, and then for all the various portions of buildings. He built a very elaborate residence at Port Chester entirely of béton and iron. He carefully investigated the proportions of the materials composing the béton for the requirements of the different parts of the structure. For floor and roof supports, the béton is enforced by iron T beams placed near the bottom of the béton beam, so as to utilize its tensile quality for resisting the strain below the neutral axis, while the béton above this line is relied on for resisting compression. Under a load of 9500 pounds, placed in the center of a béton and iron beam 12 feet long the deflection was only seven sixteenths of an inch, the beam returning to the original line after the load had been removed. Mr. Ward suggests an inverted ⊥ beam for the iron in future works. The floors of the Port Chester building were made of a one-inch layer of béton upon which iron rods five sixteenths of an inch in diameter were placed eight inches apart, both

Digitized by Google

longitudinally and laterally. On the top of this came a two-inch layer of béton, over thirteen thousand square feet of flooring and roofing being thus constructed. For the walls, Mr. Ward recommends the thin double-wall system; and for heating the buildings, he places a large number of pipes in walls and floors communicating with a central heater, thus securing uniformity of temperature and good ventilation. The reinforced béton system has also been employed with good results in heavy foundations for stationary engines, a 250 horse-power, tandem compound engine, of very heavy pattern, having been mounted by him on a reinforced béton bed, 23 feet long, 5 feet wide, and 7 feet deep. He also mounted the out-board bearing of the main shaft on a single block of the same kind, the entire cost of the foundation chamber being less than the estimate for the same in first-class brick or stone mason work.

Mr. Ward's elaborate paper which contained many facts which lack of space does not allow us to allude to at length, excited considerable interest, remarks on its contents being made by Messrs. Barnet le Van, Root, Weightman, and Thompson.

In the absence of Mr. H. R. Towne, of the Yale & Towne Manufacturing Company, Stamford, Conn., his paper, Cranes—a Study of Types and Details, was read by a member. It is a valuable summary of the results of every practical experience, for which we shall make room in an early issue. Though long, it was listened to with close attention, and called forth an animated discussion, which added to the regrets that the writer was not present. The closing minutes of the session were occupied by an earnest but rambling speech by Mr. Thomas R. Morgan, Sr., of Morgan, Williams & Co., Alliance, O. Mr. Morgan took exception to the conclusions arrived at in important matters of detail by Mr. Towne; but in his earnest efforts to impress the members with his determination to give them facts, did little beyond reiterating the statement that a traveling crane, built by him for the Dickson Manufacturing Company, embodied features meeting all the requirements of such work. Mr. Morgan received a respectful hearing, to which his long experience and the excellent work turned out by him fully entitled him; and his promise to put on record what he had to say in the Proceedings of the society gave much satisfaction.

THE THIRD SESSION.

The adjourned discussion of Mr. Towne's paper on cranes was again taken up, Mr. W. F. Durfee, of Bridgeport, Conn., leading off with the description of a cheap traveling crane built by him, for the special purpose of removing the rolls from their housings in a train of rolls. Mr. Walker, of the Walker Manufacturing Company, Cleveland, dwelt upon the results of some investigations recently made under the auspices of the government, in reference to the winding on drums of chains, the result of which was, that the frequent breakage of chains could be averted by so arranging matters that the horizontal links did not twist.

Mr. George W. Maynard, of New York, then followed with a paper on the Bower-Barff Process, in which he summarized the data submitted in earlier papers by Professor Barff and the Bowers, father and son, and gave the latest results attained in recent American practice, the few months of active work here having led to many modifications of detail, insuring better work. This paper too brought out a lively discussion, in which Messrs. Henning, Smith, Partridge, E. D. Leavitt, Jr., Hand, Weston, and Root took part. The president, Mr. Leavitt, spoke of the difficulty he had experienced in preventing the corrosion of the brass tubes in the superheaters designed by him, in which the question of the corrosive action of sulphurous acid gas from fuel came up.

Mr. William J. Baldwin, of New York, then, in a paper entitled Standards in Pipe Fittings, made a plea for the establishment of a standard in elbows, tees, and crosses, and referred at length to the scale advocated by the late Robert Briggs. While in the main coinciding with him in the necessity of such a reform, the opinion did not seem to prevail that the appointment of a special committee to report on the subject would be the best means of agitating the subject.

Mr. William Kent, of Pittsburg, in a paper on the Relative Values of Bituminous Coals, pulled the recent report made under the auspices of Quartermaster-General Meigs to pieces, and gave some general hints as to the best method of burning, particularly those coals containing between 20 and 40 per cent of volatile matter. He submitted tables showing the results of evaporation tests made with a number of American and foreign bituminous coals in Babcock & Wilcox boilers.

Mr. C. C. Collins, of the Stearns Manufacturing Company, Erie, Pa., followed with a paper on Balanced Valves; and Prof. J. B. Webb, of Cornell University, on Reuleaux's Kinematic Models.

Before adjournment, Mr. J. F. Holloway announced that he had received a dispatch from Prof. R. H. Thurston, of the Stevens Institute of Technology, which at its commencement this week conferred the honorary degree of Doctor of Engineering on E. D. Leavitt, Jr., President of the American Society of Mechanical Engineers. This announcement was received with much applause. After a brief reply by the doctor, the meeting adjourned.

In the evening, the members attended a reception tendered them by citizens of Cleveland.

AMMONIO-PHOSPHATIC DEPOSIT IN THE VICINITY OF CAPE TOWN.—Writing to the *Chemical News*, Mr. A. B. Griffiths reports on a deposit which was found some time ago in some caves, a few miles to the southeast of Cape Town, South Africa. The deposit is in a powdered condition, and of a brown color, but contains solid nodules. These nodules present the appearance of contortions like ordinary guanos; and when reduced to powder, and washed in distilled water, and the sediment treated with acids, followed by washing in water in the usual way, a microscopical examination showed that these nodules contained a large amount of diatomaceæ, and a few sponge spicules. The powder-deposit also showed the presence of diatomaceæ. On submitting a fair sample of the deposit to analysis, it was found to contain: 70·21 per cent of ammonium compounds, 17·5 per cent of phosphates, 3·3 per cent of nitrogen, etc. Probably these deposits may furnish a very useful manure. From these observations it is most probable that these deposits consist of the more or less altered excrementitious matters of an extinct fauna.

FURNACE, MILL, AND FACTORY.

The Rosedale, Kansas, iron-works have started up for a short run. The mill is to be sold in October for the benefit of the stockholders.

The new Taylor-Langdon ore-roasting furnace, erected by W. J. Taylor & Co., at their Chester, N. J., furnace, is averaging 40 tons per day of thoroughly roasted ore.

The Dickson Manufacturing Company, of Scranton, has been awarded the contract to furnish the Calumet & Hecla Mining Company, Michigan, with a steel boiler 90 inches in diameter, 36 feet in length, and to carry 150 pounds pressure. The total weight of this boiler will be 108,000 pounds, and the castings for it will weigh 10 tons. It will have 199 three-inch tubes.

A stock company has been formed in Harrisburg, with a capital of $35,000, for the manufacture of edge tools.

The Parkersburg Iron Company, Pennsylvania, has erected a steam-hammer that weighs 47,000 pounds.

The Maumee Rolling-Mill Company, Toledo, Ohio, is building a mill which will be in operation by January 1st, 1884. The capital stock of the company is $500,000.

The new Crozer Furnace, at Roanoke, Virginia, made a very successful start on May 28th. The first cast was a gray forge of fine quality and great strength, weighing about eight tons. The daily output is expected to be from 80 to 100 gross tons.

The Shelby Iron Company, Alabama, having two blast-furnaces at Shelby, is experimenting with the Mathieu process of making charcoal. By this process the by-products are saved.

A company with a capital of $200,000 is forming at Mobile, Alabama, for the purpose of establishing a pig-iron furnace with a capacity of sixty tons daily.

The California Iron and Steel Company has just blown in its new blast-furnace at Hotaling, Placer County, Cal. The buildings are iron and have the latest improvements.

It is understood that the directors of the Puget Sound Iron Company have in contemplation the building of a large rolling-mill at Irondale, Washington Territory.

A company of Toronto capitalists is proposing the erection of blast-furnaces in that city, and has appealed to the Dominion Minister of Finance for higher duties and an increase of the promised duty of $1.50 per ton on pig-iron of domestic manufacture.

The Blakeney Foundry Company, of Springfield, Ohio, recently organized, is building extensive works at that place for the manufacture of the Blakeney cupola-furnaces and general castings.

The Missouri Malleable Iron Company, of St. Louis, Mo., has recently put its works into full operation. The works are supplied with the latest and most improved machinery and apparatus for turning out a general line of malleable castings for agricultural and other castings.

The McKenney Tubular Rail Company, of Chicago, recently incorporated, has located its works at La Grange, Lewis County, Mo., where the necessary buildings are in course of erection.

The converting-works and rail-mill departments of the Chicago works of the North Chicago Rolling-Mill Company have started up with from 700 to 800 men. All other departments of the works at South Chicago and Bay View, Wis., are in operation.

The Link-Belt Machinery Company, Chicago, is building a hay-conveyor for Hall, Warner & Co., Wellington, Ohio; one large conveyor and elevator for the Cincinnati Linseed-Oil Company, Cincinnati, Ohio; an ear-corn conveyor to go to Beloit, Wis.; one stone-conveyor for W. A. L. Thompson, Topeka, Kansas; and a grain-weighing and transferring-car for Wells, French & Co., of Chicago.

MINERAL PATENTS GRANTED BY THE UNITED STATES LAND-OFFICE.

The following mineral patents have been promulgated from the General Land-Office under date of June 1st, 1883:

ALABAMA.

HUNTSVILLE DISTRICT.

The placer claim of Stephen E. Dobbs, De Kalb County.

ARIZONA.

TUCSON DISTRICT.

Louis C. Hughes *et al.*, Copper Queen lode.

CALIFORNIA.

MARYSVILLE DISTRICT.

John C. Gray, Good Luck placer mine.

SACRAMENTO DISTRICT.

George David Endriss, placer, El Dorado County. Christopher Buddecke, Strap Ravine placer mine, Placer County. George Nichols, placer, Calaveras County.

SHASTA DISTRICT.

Louis F. Roab, Roab & Perkins Bar placer mine, Trinity County. George Simmons and James Quinne, placer, Siskiyou County. John D. Mello *et al.*, placer, Siskiyou County.

SUSANVILLE DISTRICT.

Plumas Eureka Mining Company, Amador placer mine, Plumas County.

COLORADO.

CENTRAL CITY DISTRICT.

R. W. Knowles, Syndicate, Golden Rule, and John Sherman lodes. Pizarro Gold and Silver Mining Company, Pizarro and Pizarro Extension lodes. William W. Flagg, Atlantic lode. John Hunneau, Mary Ann lode. Charles A. Martine *et al.*, Cuba lode and mill-site. James Lotridge *et al.*, Silver Star lode. J. Wesley Miller, E. W. Lyon lode and mill-site. Lewis C. Snyder, Egyptian Side lode. Ernest Stahl, Kalamazoo lode. Ivers Phillips, placer, Boulder County. Albe M. Saxton, Keystone lode. D. J. Hutchinson *et al.*, Bonanza lode. William M. Roworth, Stewart & Company lode. Hal Sayr, Rainbow and Sans Souci lodes. Henry M. Teller, Running lode, West lode. Hal Sayr *et al.*, Valverde lode.

DURANGO DISTRICT.

Simon H. Stern, Crown Point lode. N. J. Bradley *et al.*, Uncle Ned lode.

LAKE CITY DISTRICT.

Isaac Thomas, Ophir lode. Rico Silver Mining Company of Colorado, Bobtail lode. Desire Friend *et al.*, Independence lode. C. E. Schoellkopf, Oriental lode. Thomas C. Wilson, Ben Bolt lode. Engineering, Mining, and Developing Company, Mountain Monarch No. 2 lode. David Geiger *et al.*, Monarch lode.

LEADVILLE DISTRICT.

W. G. Reid *et al.*, W. G. Reid lode. Americus L. Pogue, Galena lode. Roswell Sprague Jones, Westmoreland and Harrison lodes. Abia G. Hooper *et al.*, Governor lode. Lennox Mining and Milling Company, Kansas City No. 2 lode. Canada Consolidated Mining Company, Eva, Little Rose, Little Maud No. 2,

Digitized by Google

Little Lulu, Lady Elgin, and Little Bell lodes. Abraham Jacobs *et al.*, Why Not lode.

PUEBLO DISTRICT.

Game Ridge Consolidated Mining Company, Times lode. James A. Melvin *et al.*, New Year lode.

DAKOTA.

DEADWOOD DISTRICT.

Samuel McMaster, Little Nettie lode.

IDAHO.

BOISE CITY DISTRICT.

William H. Nye *et al.*, Idahoian lode.

MONTANA.

HELENA DISTRICT.

John McLaggan *et al.*, Simon lode. Nathan S. Vestal *et al.*, Empire lode and mill-site. Edward B. Corely *et al.*, Keystone lode. Edward Hickey *et al.*, Black Hawk lode. Thomas Cruse, North Star lode. Thomas Wilkinson *et al.*, placer, Lewis & Clark County. James D. Heald, placer, Madison County.

CARSON CITY DISTRICT.

Manuel San Pedro *et al.*, Arctic lode. Luther A. Buckner, Montgomery lode.

NEW MEXICO.

LAS CRUCES DISTRICT.

The Sterling Price Mining Company, Sterling Price and South Virginia lodes. William H. Henry and James B. Price, Johnny Bull lode. Daniel H. Moffat, Jr., forty-five patents upon the Santa Rita lodes Nos. from 1 to 31, both inclusive, and 33, 34, and 47, 48, 49, 50, 53, 54, 55, 57 to 61, both inclusive.

UTAH.

SALT LAKE CITY DISTRICT.

Sunbeam Mining Company, Lady Aspinwall lode. Martha Martin *et al.*, What Cheer lode.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY—TOMBSTONE DISTRICT.

Work at the various mines continues with the usual results. No important developments have been made since our last issue.

PIMA COUNTY.

COPPER QUEEN.—The production of this company for the year 1882 from the two smelters was upward of 8,000,000 pounds, with an average fineness of 96⅓ per cent, and they are still running with the same degree of success.

YAVAPAI COUNTY.

NONESUCH.—This property, discovered in 1864, and named the Goodwin, in honor of Arizona's first governor, after a series of ups and downs, has at last fallen into the hands of a company which promises fair to systematically test its merits by a proper development.

SILVER JOE.—This mine is situated near the Goodwin. The ledge has been traced for over 900 feet, and wherever uncovered shows a continuous vein, from two to eight inches in width. The lode bears north and south, and has a nearly vertical descent at all points where it has been sunk on. The ore is a chloride and sulphuret of silver, containing but very little base.

CALIFORNIA.

Dispatches from the City of Mexico state that the government has ordered troops to be sent to the new gold diggings in Lower California, for the preservation of order. The prefect of the territory has been ordered not to admit locations until he receives special instructions from the federal government. The richness of the diggings has been officially confirmed.

AMADOR COUNTY.

According to the San Francisco *Stock Report*, a suit has been begun in the United States Circuit Court by the New York Mill and Mining Company, an incorporation in the State of New York, against the Amador Mill, Mining, and Tunnel Company, of California, for the possession of 600 feet of a mining claim near Middle Bar, Amador County. The complaint alleges wrongful possession. An injunction restraining the Amador Company from working the mine is also asked for.

PLUMAS COUNTY—GREENVILLE DISTRICT.

CRESCENT.—The mill has been stopped.

GOLD STRIPE.—Work has begun at the tunnel and stopes, in order to get out what ore is in sight there. An arrangement is about completed with John McIntyre and W. Deal, by which the ledge recently discovered by them will be made available for work in the mill.

INDIAN VALLEY.—The necessary repairs on the wrecked machinery have been completed, and work has been resumed at the mine and mill.

LUCKY S.—Prospecting-work has been kept up steadily on this claim, situated in Emerald District. The mine is now so far developed that the building of a mill will be decided upon shortly.

SUN SET.—The developments continue good. Mr. C. G. Rogers, superintendent of the Green Mountain, and J. O. Hemler, have bought a half-interest in the mine.

SIERRA COUNTY.

SIERRA BUTTES.—The company has begun the erection of a new forty-stamp mill at Sierra City. It is expected that this company will employ 100 more men than hitherto.

CANADA.

A dispatch from Montreal states that a contract has been given out for the building of the Gatineau Railroad from Ottawa seventy miles up through the district where the phosphate mines are situated. The cost will be $16,000 per mile.

NOVA SCOTIA.—One of the best gold discoveries so far in Halifax County has just been made on the old De Wolf property at Montague, close to the celebrated Rose leads. Three leads, respectively 33, 11, and 7 inches in width, have been found about twelve feet below the surface, and give indications of a rich yield.

HALL-ANDERSON.—The secretary of this company has sent us the following information: The management has changed hands, owing, it is said, to a sale of a large block of stock to a syndicate. Messrs. H. K. Adams, late president, and E. F. De Camp, late general manager, have resigned their official positions, and also retired from the directory. Mr. E. D. Davidson, late acting superintendent at the mine, was elected president. He reported the mill as in a splendid condition, and the mine itself never looking better. The last ore he crushed, and with a good return, came from the Orion Belt, and just at the beginning of a big strike.

OXFORD.—The superintendent telegraphed on the 8th that he had shipped a gold brick, value $4000, from a mill-run of six days. The ore is running richer. The Split lode, just opening, promises as well as the rich Mill lode. Prospecting just east of the company's ground shows up a new and very rich lode.

COLORADO.

BOULDER COUNTY.

Important strikes have been made in the Richmond and Three Brothers mines, situated near Salina.

CHAFFEE COUNTY.

The building of the railroad is progressing steadily; the grading of the highest and most difficult points along the route is pushed with vigor, the level and easier portions being left for later on in the work. Under such circumstances, the casual appearance of progress is deceptive to those expecting to find tracks laid and the road within the promised time, thus putting Chaffee City, which will then be known as the Monarch, in direct communication with the railroad lines of the United States.

CLEAR CREEK COUNTY.

CAMPBELL.—The managers announce the want of a sufficient amount of the right kind of ore as the cause of the delay in starting the smelter at Idaho Springs.

DIAMOND JOE.—Work will be resumed.

DIAMOND TUNNEL.—The No. 5 lode is opening an excellent streak of ore. The vein has shown continued improvement since passing the horse, and the work ng force has been increased. The prospects look well for a large ore-body. The Corry City veins are also showing more encouragement. Rising has been commenced on No. 2 with a streak of scattered ore, which grows larger as work progresses. No. 3 is showing ore coming in more plentifully in places across the drift heading, with evidence of being near the horse.

LITTLE JACK.—A vein of mineral, containing a great deal of gray copper, has been opened up on this lode.

MATILDA FLETCHER.—The lessees propose to sink a shaft below the lower level. It is already fifty feet down, and when it reaches a depth of sixty feet, drifting will be commenced on a good pocket of ore which has yielded largely in the upper workings in the past.

DOLORES COUNTY.

SILVERADO.—The recent strike of copper ore shows a vein two and a half feet wide. The company owns twenty-one claims and considerable other property.

EL PASO COUNTY.

There is considerable excitement in Colorado Springs on account of a rich mineral strike in the Mount Pisgah District, about thirty-five miles southwest of Colorado Springs. It is stated that there are already over one hundred prospectors at work, and others are coming in rapidly. The mineral found is said to be rich gold-bearing rock.

GUNNISON COUNTY.

MOFFET REDUCTION-WORKS.—The desulphurizing furnaces of these works at Gunnison City have been started up and are working well. The water-jacket blast-furnaces of the establishment are to be blown in shortly.

HINSDALE COUNTY.

CROOKE'S MINING AND SMELTING COMPANY.—Concentrates at the rate of 20 tons a day are stored in bins near the smelter. Drying by artificial heat has been stopped. Both sides of the concentrator are running, and will soon be delivering 40 tons of concentrates a day.

GOLDEN WONDER.—The important suit involving part of the property of the Golden Wonder syndicate, which was to have been tried in Denver, has been compromised in Mr. Alvord's favor. The owners of the property expect soon to be ready to push development and put in a stamp-mill.

OHIO CONSOLIDATED.—J. B. Downman is to take charge of this company's property. An examination of the Dolly Varden and other properties of the company will be made and assessments worked.

LAKE COUNTY.

Late Leadville exchanges report the following:

ARKANSAS VALLEY SMELTER.—Four furnaces are in blast. Numerous improvements are making at the works; and to assure a constant and desirable supply of water, connection has been made with the large reservoir of the American Smelting Company, and a new reservoir has also been constructed near the works, 80 by 125 feet, and six feet in depth.

CHRYSOLITE.—A strike of substantial dimensions is reported from the Muldoon shaft, which is developing by lessees.

ELGIN SMELTER.—The works have lately been overhauled and put in first-class running condition by the Manville Smelting Company. The establishment has begun to receive ore, and at the present time the ore-platforms contain considerable fine smelting ore, to which additions are made daily. The equipments of the smelter have been improved by the addition of a new pair of Cornish rolls, the enlargement of the ore-bins and rearrangement of the machinery generally.

EVENING STAR, AND MORNING STAR.—A body of ore of considerable importance has been opened in the Evening Star mine on the line of the Morning Star Consolidation. The mineral is a dark oxide of iron and galena, having an average value—determined by six or eight assays—of about one hundred dollars to the ton. The discovery is some distance from any of the previously opened ore-bodies in the Evening Star, and sixty feet west of any opened ground in the Morning Star. The new McHarg shaft of the Morning Star lode has attained a depth of 391 feet.

LITTLE CHIEF.—During the past month, twenty-one hand-jigs have been placed in Big Evans Gulch, a few hundred yards from the mine, and at present over one hundred tons of dump material are sent to the jigs daily. From six thousand to ten thousand tons of waste rock now encumber the premises of the Little Chief mine, a great deal of which is worthless for any other purpose than concentration. In the system adopted, this material is concentrated on an average of from ten to fifteen tons into one, and a product obtained ranging in value from 40 to 50 ounces in silver, and from 12 to 20 per cent in lead.

TENDERFOOT.—This property, whose record as a producer is yet in its infancy, is in good condition. The amounts shipped have consisted of that which was taken from the path of development without a particle of stoping, and netted thirty ounces per ton. There are upon an average four feet of hard and sand carbonates, with now and then a stringer of quartzite that carries from half an ounce to two ounces in gold. A contract has been let for the sinking of the shaft fifty feet deeper, and from that point another drift will be run to cut the body, which has already been proved up in the upper level.

PITKIN COUNTY.

Mr. Gilaspie, one of the principal mine-owners of the district, is negotiating for himself and other mine-owners of Pitkin County, for a lease and option on the Aspen smelter. The works were recently erected by a company from Texas, and are now offered for sale. The establishment is complete in every respect,

Digitized by Google

ready for blowing in at a day's notice, possessing even the necessary fluxes, coke, and charcoal. In the absence of cash capital with which to place the works on a basis for a good start, in the event they can be secured, it is proposed to form a company which shall pay its capital in ore.

Brooks, Bethune & Wemel's smelter at Ashcroft has been blown in and makes a successful test-run.

CASTLE PEAK MINING AND SMELTING COMPANY.—The machinery will not be started this season. The company owns a number of valuable properties, all of which are patented, and this year will expend its capital in development, to change them from prospects to mines.

SUMMIT COUNTY.

A letter written from Kokomo shows that the most pressing need of Ten Mile District is sampling-works. The larger mines ship their product in car-lots to the smelters at Leadville, Cañon City and Denver; but the prospector who takes out a ton or two while doing his assessment-work is practically without a market. The writer states that it is not an extravagant assertion to make, that there are to-day a thousand tons of different graded ores lying on the dumps of what are known as non-producing mines, within a radius of two miles from Kokomo, which would be brought in and sold if there was market for it. The concentrating-works of Mr. Greer are now handling about eighty tons of Robinson low-grade ores.

DAKOTA.

FATHER DE SMET.—The secretary writes, under date of May 27th, as follows: Herewith express company's receipt for bar No. 159, containing 673·40 ounces of gold, the result of run of mill for the first half of May. We have just passed through one of the worst floods that this country has ever seen. It did not injure the mine or mill belonging to this company, except causing a stoppage of the mill for three days, caving of cuts, shafts, and winzes, which we are now removing, and crushing *débris*, which will pay very little, thereby making shipments for May very light. All the roads and bridges in the hills are swept away, causing supplies to be very short and high in price. However, we are now supplied, so that the mill can be run steadily and at a profit. On the 15th inst., I drew for $18,500 for April expenses. The bullion did not leave Deadwood until the 26th inst. Ore extracted from first, second, third levels, 2840 tons. Ore milled, 2790 tons. Golden Gate north-header advanced 14 feet, making 31 feet for the month. Header in 125 feet. Tramway level rise for the month 15 feet. Rise up 74 feet.

GEORGIA.

CHESTATEE.—Thirty stamps are now running regularly, producing satisfactory results. Some trouble is, however, experienced with the water, the supply of which is not at all times as plentiful as could be desired.

COLUMBIA.—The new pump is forcing water from the Hand Ditch to the new reservoir.

FISH TRAP.—Prospect-work is continued.

IDAHO.

According to the Salt Lake *Tribune*, mining operations are progressing at Snake River. At Eagle Rock, a short time ago, some men made an apparatus for saving the fine or flour-gold, which is so plentiful in all the gravel-beds in the valley of that stream, and they have apparently solved the question of how to save this gold. Their apparatus consists simply of a sluice-box with a portion of the bottom constructed of an iron plate having numerous small perforations, for the purpose of permitting the black sands and fine gold to pass through and drop into a box beneath, while the coarse gravel, earth, etc., is washed out at the end of the box. The lower box has three openings on each side, with gates to regulate the flow into the three sluice-boxes running off at an angle from each side. In each of these are placed burlaps or gunny sacks, to catch the fine gold as it is washed along. The system has been found to work well, besides costing but little to adapt, is easily and cheaply operated. The amount of gold taken out per day with the first apparatus put in operation averaged between $20 and $25, and two men operated it.

MULDOON.—The furnaces are running on Muldoon ore, and turning out bullion steadily.

PHILADELPHIA MINING AND SMELTING COMPANY.—The company has from 15 to 20 six-horse teams constantly employed in hauling hematite ore from the Iron mine to its furnaces.

ST. PATRICK.—This mine has been sold to Baltimore gentlemen, who propose to organize a company.

MEXICO.

The smelting works at Mapimi, Durango, are reported to be the largest in the northern part of Mexico. By the aid of new machinery lately received, a capacity of 90 tons daily will be obtained.

BERNALEJO.—It is reported that a New York company has just closed negotiations for this Zacatecas mine, and will proceed to systematically develop it.

CIENEQUILLA.—The Chihuahua *Mail* states that these mines, sixty miles west of Chihuahua City, promise early prominence again. These mines were worked earlier than 1691; abandoned that year on account of the Indians; resumed operations again in 1696, and worked until 1832, when, on account of Indians, they were again abandoned. Under old-fashioned methods, immense fortunes were realized by their owners. Yet the mines were merely tinkered at until 1881, when the company now working took hold of them and actively pushed work, clearing out and developing the old shafts. It has employed sixty men, opened two new shafts and a vein that will average ten feet in width, and will soon equip the mines with the best modern machinery.

CONSOLIDATED MINING COMPANY.—This company's property, situated at Las Minas, Vera Cruz, owns about twenty-five mines of gold, silver, copper, and lead. The ores are low-grade, but abundant and easily worked. The company has been working for over a year. A Tasker pulverizer is operating and other machinery erecting preparatory to a large output.

MEXICAN INTERNATIONAL DEVELOPMENT COMPANY.—This company, which, as mentioned in our last issue, organized at Guanajuato, proposes to develop gold, silver, and other mines; to make loans on good properties; to beneficiate metals of mines belonging to the company and others; to drain mines and to do other work pertaining to the industry.

PACHUCA RIVER REDUCTION COMPANY.—The company has received two Frue vanner concentrators, which will be erected at once. The company is taking in the "tailings" from the river-bed, in anticipation of the rainy season.

ROSARIO.—The mine has been drained of water. The shaft proves to be only 250 feet deep.

ZIMAPAN COPPER COMPANY.—At a recent meeting of this company, it was resolved to send to Swansea, England, for a copper refiner and furnace builder.

MICHIGAN.

The following are the returns of the reporting mines for the month of May:

	Tons.	Lbs.
Calumet & Hecla	1837	1490
Quincy	261	40
Franklin	170	25
Atlantic	162	385
Allouez	102	985
Pewabic	70	450
Peninsula	58	600

CONGLOMERATE.—Mr. Thomas has resigned his position as superintendent. Mr. S. W. Hill will succeed him.

JOHN DUNCAN LAND AND MINING COMPANY.—The financial statement presented at the annual meeting shows cash paid in, $40,000; real estate purchased, $36,803.10; expenses, $827.59; leaving cash on hand, $2369.31.

MONTANA.

GALLATIN COUNTY.

LARD HYDRAULIC COMPANY.—The company is said to have an abundant ca work its gravel deposits, which vary in depth from 50 to 150 feet.

JEFFERSON COUNTY.

BANNER.—This mine is tapped by two tunnels, 600 feet apart, at a depth o about 100 feet from the surface. The lower tunnel is extended along the vein 300 or 400 feet, exposing a body of ore from one to three feet thick. Levels are run each way along the vein, from where the upper tunnel strike shows a strong vein of good ore.

GREGORY.—The shaft has now attained a depth of nearly 600 feet, and work is prosecuted on the 300, 400, 500, and 600-foot levels. In all of these levels, a strong vein of high-grade galena ore is exposed. The company anticipates increasing its concentrating capacity by erecting a ten-stamp battery. It also contemplates putting up new hoisting-works when these improvements are made. It is expected that the roasters and smelters will run steadily.

NELSON.—This lode is an old location, having been discovered in 1872. The ore-vein is cut by two tunnels, one tapping the lode 200 and the other 300 feet from the surface. Levels have been run from each tunnel along the vein several hundred feet.

ROBBINS.—This property adjoins the Banner on the east. It has a shaft fifty-eight feet deep; the bottom of the shaft is in good ore, of the same character as that of the Gregory.

SOLO.—The vein cuts the tunnel seventy feet from the surface. The vein is six feet wide, containing a mixture of free-milling and smelting ores, which assay well.

STANDARD.—Not much development-work has been done at this mine. Two open cuts have been run to the lode, exploring the vein twenty feet from the surface.

NEVADA.

HALE & NORCROSS.—The official letter, dated June 4th, shows that the winze is sunk to a depth of 20 feet below the 2600-foot level and three sets of timbers have been put in place. At a distance of about 8 feet down, we encountered ore on the west side of the winze, which still shows at the bottom. This ore seems to be a new stringer, east of that shown at the station level, or it may be a widening of that ore. There is some water in the winze, which is easily handled with a donkey pump. This winze water is evidently a portion of the water that we already had on this (2600) level, as there is no increase in the quantity flowing from our ground to the joint shaft.

NORTHERN BELLE.—The superintendent writes that there is no change of note in the formation on and below 5th shaft level. The southwest drift has been extended 8 feet, now in 106 feet. The streak of sulphuret mentioned last week shows an increase of width and also in value of assays from same. On 4th level, the stopes continue to look well and are yielding as usual. No change in drifts and cross-cuts on this level. In uprise above 1st, the stopes are producing some very fine ore and the outlook is quite promising. In other shaft levels, there are no changes of importance. Section of the mine above the adit presents about the same appearance as last reported. From stopes on 7th and 9th, we are extracting some ore of fair grade. Every thing is running smoothly at the hoisting-works, and all work in the mine is progressing in a satisfactory manner.

NEW MEXICO.

HUBBS'S SMELTER.—Three car-loads of rich ore have been received from Silver City. During last week, there were delivered at the smelter seven car-loads of this same ore, and shipments are now on the way from the same parties. The Silver City ore will continue to be sent. The smelter would have been started up and kept running were it not for the absence of any galena ores with which the harder Silver City ores could have been smelted. Galena ore is now purchased for that purpose.

NORTH CAROLINA.

CAMPBELL MINING AND REDUCTION COMPANY.—A correspondent of the Chicago *Mining Review* announces the temporary stoppage of work on this company's tract, nine miles from High Point, and adds that it would have been better for the company to be satisfied with the exploitation of the large and productive vein on its original tract, of nearly 200 acres, instead of adding constantly by purchase, more than it was able to work.

HOOVER.—It is stated that the production so far this year has amounted to 500 ounces of gold.

UTAH.

CACTUS.—At the annual meeting, held in Salt Lake City, the following directors were elected: A. G. Campbell, A. Byran, Count d'Adhermar, Albert de Lautrippe, the latter two of Paris, France; W. H. Burnison, H. W. Morse, and H. C. Woodrow. After this election, the board selected for officers A. G. Campbell, President; H. C. Woodrow, Vice-President; H. W. Morse, Secretary; and J. E. Dooly, Treasurer. The concentrating mill belonging to this company is ready for work, and has a capacity of fifty tons of crude ore per day, with surplus power to more than double by adding more machinery. At present, twenty-five men are employed in the mine.

DALY.—This group of mines, lying west of the Ontario, comprises twenty-five patented claims, covering about 150 acres of surface. On these claims, to this date, about $78,000 have been expended, and now the property is in a fair way for production. A two-compartment shaft will be sunk at a depth of several hundred feet for the purpose of developing a vein which has been prospected by tunnels for several years, and which has been proved a distance of 5000 feet.

GREAT EUREKA.—This property is producing about thirty tons a day, which it is said will net, after paying mining and shipping expenses, $30 per ton.

HIDDEN TREASURE.—The tunnel is still driving to the lower workings. It will be remembered that it was formerly a great producer, running the old Waterman smelter at Rush Lake for several years. It was worked from the top of the hill, where the series of caves filled with ore came to the surface, and the ores run down on a wire tramway. The mine can be worked to much better advantage from the tunnel, which is expected to tap the old workings within two months.

MAMMOTH.—The difficulties at this mine, according to the Salt Lake papers, have not been settled.

TINTIC.—The mill is supplied with ore mostly from the company's mine, the Northern Spy, which produces a large amount of milling ore.

TRUE FISSURE.—This company owns the Frisco mine at Bingham, and twenty acres of placer ground adjoining. The property came into the hands of its present owners in October last. The ground had been worked last on a lease, and the lessees had left the workings in a dilapidated condition. But a comparatively small expenditure soon put the mine in working order. At present, eighteen men are at work; and it is expected to increase this force to forty or fifty as soon as the new tunnel and air-shaft are through.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, June 15.

There is nothing of interest to note in the mining market this week. Business continues to be very dull, and prices have been very irregular. Sonora Consolidated continues to be the favorite stock dealt in, and has suffered a still further decline. Decatur is another fancy largely dealt in, but its price did not materially change. Sierra Grande has been more actively dealt in than of late, but it seems to be impossible to uphold the strong prices of last week. Robinson has been almost neglected, and the price has remained steady. A complete summary of the market is given below. The total number of mining shares sold at all the Exchanges aggregates 176,418 shares, as against 196,662 last week.

The Comstock shares were quiet at about steady prices. California sold to the extent of 3150 shares at 36@42@37c. Consolidated Virginia had a small business at weak prices; it sold from 80@68c. Sierra Nevada was weak; with a moderate business, it sold from $7.88@$6.50. Union Consolidated has been strong, under moderate transactions, selling from $8.63@$9. Ophir sold at $4; Yellow Jacket at $5.13; and Best & Belcher at $5.50, with one small transaction each. Consolidated Imperial was quiet and steady at 9@10c. Sutro Tunnel was active and irregular, selling from 29@24@25c.

The Leadville stocks were but moderately dealt in, and were steady. Amie was quiet and irregular at 18@16@17c. Chrysolite had a small business at steady prices, selling from $1.15@$1.20. Iron Silver records a moderate business, and was steady; it sold from $2.90@$2.85. Leadville sold at 50c., with a small business. Little Chief was quiet and strong, selling from 49@55c. Little Pittsburg sold at 78c., with transactions of 500 shares. Climax sold at 7c.

The Bodie stocks were almost entirely neglected. Bodie Consolidated was dealt in to the extent of 1640 shares at $1@92@95c. North Standard was quiet and steady at 8@10c.

The Tuscarora stocks were quiet and steady. Grand Prize sold at 25c. Belle Isle was quiet and steady, selling at 20c., assessment unpaid, and from 42@40c., assessment paid. Navajo had a small business at stronger prices; it sold from $1.45@1.80. North Belle Isle was quiet and steady, selling from 20@25c. Independence sold assessment unpaid, and was quiet and steady at 33@30@32c. Elko Consolidated records a moderate business at steady prices, selling from 19@18c.

In the miscellaneous list, Bassick has been moderately dealt in at very irregular prices; it sold from $10@$9.25@$9.50. Caribou Consolidated was quiet and steady at 14@13c. Eureka Consolidated records a small business at strong prices, selling at $4. The Green Mountain stocks have been quiet and steady. Gold Stripe sold from 7@8c. Green Mountain sold at 73c., and Rising Sun at 3c. Homestake was quiet and steady at $15.75@$16@$15.63. Horn-Silver had a fair business at irregular prices; it sold from $6.63@$6.25@$6.38. Northern Belle has been weak, under moderate transactions, selling from $6.75@$6. Robinson Consolidated has been very quiet at steady prices, selling from 77@75c. Sierra Grande records a fair business at very irregular prices; it sold from $1.50@$1.25@$1.30, the business aggregating 7700 shares. Stormont has suffered a decline, under a small business, selling from 69@48c.

Alta-Montana was quiet and steady at 3@4c. Bradshaw was quiet at 26c. Caledonia had a small business at strong prices; it sold from 75c.@$1. Decatur records a very active business, and has been steady, selling from 5@4c. Eastern Oregon records a fair business at strong prices; it sold from 31@38@35c. Harlem was quiet and steady at $1.40. Oriental & Miller sold from 16@18c. under a small business. Rappahannock sold from 6@8c. Sonora Consolidated continues to decline under a very heavy business; it sold from 34@24@25c., with a business of 53,900 shares. State Line Nos. 1 & 4 was quiet and steady at 4@5c.

MEETINGS.

Bassick Mining Company, No. 44 Wall street, New York City. Annual meeting of stockholders and election of trustees, June 26th, at twelve o'clock M.

Great Eastern Gold Mining Company, No. 64 Broadway, New York City. Annual meeting of stockholders, June 16th, at eleven o'clock A.M.

Wide West Mining Company, No. 32 Park Place, New York City. Annual meeting of stockholders, June 16th, at twelve o'clock M.

DIVIDENDS.

The Carbonate Hill Mining Company, of Colorado, has declared dividend No. 6, of five cents per share, payable July 2d, making the total dividends declared to date, $60,000.

The Crescent Mining Company, of Utah, has declared a dividend of ten cents per share, or $50,000, payable June 20th.

The Hecla Mining Company, of Montana, has paid its regular monthly dividend (for May) of fifty cents per share, aggregating $15,000.

The Homestake Mining Company, of Dakota, has declared its usual dividend of $50,000 (for May), payable at the office of the transfer-agents, Messrs. Lounsbery & Haggin, Mills Building, on June 25th. Transfer-books close June 20th. Total of dividends to date, $1,162,500.

The Indian Queen Mining and Milling Company, of Nevada, has declared a dividend (No. 31) of one and a half per cent upon the capital stock of the company, payable July 2d.

The Kentuck Mining Company, of Nevada, has declared a dividend (No. 38) of ten cents per share, payable June 20th.

The Silver King Mining Company, of Arizona, has declared a dividend of twenty-five cents per share.

The True Fissure Mining Company, of Utah, has declared a second quarterly dividend of twenty-five cents per share, payable June 15th.

PIPE LINE CERTIFICATES.

Until yesterday, the petroleum market was dull and featureless. Throughout the week, oil has been dull, the fluctuations being very irregular. Yesterday and to-day saw better prices and a strong "bull" market.

There is but little news from the oil regions. On Tuesday, Patterson Well No. 8 was reported as good for 300 barrels the first twenty-four hours, but later news estimated it from 100 to 150 only. It is said that the patent on the Roberts torpedo expired on May 20th, and that the reduced price on this article has increased its use in the wells. The Cooper tract is said to have declined 900 barrels in production during the past week. To-day's dispatches quoted Anchor Well No. 19 as having given 120 barrels the first hour. Later news, however, states that the well has declined rapidly, and is producing only 18 barrels per hour. The decline in this well, and the fact that the syndicate had made certificates scarce in Oil City, and that the loaning rate was down to thirty cents, or twenty cents below the actual cost of storage, led to-day to a firm and pronounced bull feeling, under which the market was strong.

The annual election for officers of the New York Mining Stock and National Petroleum Exchange was held on Monday last, and the following persons were chosen: President, C. O. Morris; Treasurer, John Stanton; Chairman, A. W. Peters; Secretary, P. J. Sweeny, Assistant Secretary, R. H. Gallaher, Jr.; Members of the Governing Committee, to serve one year: C. G. Fales and Julius Jahn; to serve three years: A. W. Peters, S. V. White, J. A. McPherson, J. S. Stanton, Leo Speyer, J. R. Mullany, F. F. Beals, L. V. De Foreest, and C. L. Parker; for Trustees of the Gratuity Fund, to serve one year: C. F. Woods; to serve five years: S. V. White and Henry H. Truman.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
June 9....	$1.15⅛	$1.19⅜	$1.15¼	$1.18⅜	2,480,000
11....	1.18¾	1.18⅞	1.16	1.16½	2,628,000
12....	1.16½	1.17⅛	1.15¾	1.16⅝	1,248,000
13....	1.16⅞	1.18⅝	1.16¾	1.17⅝	1,744,000
14....	1.17⅝	1.20⅝	1.17⅝	1.18⅝	2,453,000
15....	1.18⅜	1.19⅞	1.17¾	1.19⅜	3,122,000
Total sales.					13,675,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, June 14.

The market for copper stocks this week has evidently turned, showing decided improvement in several, notably Calumet & Hecla and Quincy. The fact is, prices have ranged too low for some time past, and it is quite clear that the best companies can continue to pay good dividends, even with the price of copper at 15c. Calumet & Hecla has advanced steadily from $287½@$243 bid. Even this price does not bring out the stock; it is remarkable how little of it comes on the market, the sales the past week being only four shares. Allouez seems to be an exception to the market, and finds little favor, with small sales a $1⅞. Atlantic at $11 is the first sale for over month, and the stock is in fair demand at that price. Franklin, which has remained very dull for weeks at $10, has become quite active again, advancing to $10½. Of Huron and National, there are no sales, nominally $1⅛ bid. Osceola declined from $20½@$19¼, ex dividend 50 cents, payable July 1st. This company has heretofore paid $1 per share quarterly—now reduced one half. Pewabic, without sales previous to this week, since May 22d; at $3, has started into life again, advancing to $4, and same bid. The accounts from the mine continue encouraging, and it is among the possibilities that this company may "strike it rich" almost any time at very short notice. Quincy, which was working up a little last week, and had gained from $44@$45, farther advanced to $50, with a good demand for the stock through the week. The general expectation that this company will divide $3 per share in August gave strength to the stock, and the upward price has been accelerated by the forcing of a short interest to cover.

In silver stocks, there is a better tone, without any great activity. Bowman is assuming prominence, and advanced from 17@22c. The stock is very strong as it moves up, and it would not be surprising to find it selling at 50 per cent advance on the present price within a few weeks. Sullivan suddenly dropped from $1⅞@$1½, at which 500 shares were put out; later, it is back to $1⅞, and the same bid. Catalpa, which had been exceedingly quiet for some weeks, with scarcely any sales, has suddenly started up from 65@70c. Crescent follows in sympathy, and has reached 30c. The improvement in both is due to the better prospects at the mines, assisted by a speculative movement. Bonanza has advanced from $2¼@$2½; and later, $2⅝ bid. The agent of this company is now in England, on a mission to sell a portion of its property, which, if successful, should greatly enhance the market value of the stock.

3 P.M.—The market this afternoon continues firm, and prices are well sustained. There were large sales of Catalpa (3550 shares) at 65@70c., closing at latter rate bid. Calumet & Hecla, $243 bid. Franklin, $10¼. Pewabic, $4. Quincy receded to $49½, and was offered at that. Silver Islet sold at $4, and same bid, but the stock seems to have few friends.

BULLION MARKET.

NEW YORK, Friday Evening, June 15.

The London market is steady and somewhat firmer, but rather inactive, and sterling exchange here is likely to decline the coming week, thus probably neutralizing any advance in silver abroad.

DATE.	London Pence.	N. Y. Cents.	DATE.	London Pence.	N. Y. Cents.
June 9.	50 1-16	109⅝	June 13	50⅛	109¾
11.	50 1-16	109⅝	14	50⅛	109¾
12.	50 1-16	109⅝	15	50⅛	109¾

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14⅛ per cent, to arrive at actual value.

MINES.	States.	Month of May.	Year from Jan. 1st, 1883.
*Alice, G. S.	Mont.		$320,419

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended June 15th, as compiled from various sources, amounted to $151,000, as against $174,000 reported for the previous week. The receipts from January 1st, 1883, to date are $5,560,713.53.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended June 9th	$99,828
Corresponding week last year	2,526,451
Since January 1st, 1883	5,945,734
Corresponding period last year	31,683,999

Imports.

Week ended June 9th	$26,144
Corresponding week last year	62,096
Since January 1st, 1883	6,789,083
Corresponding period last year	1,794,749

Foreign Bank Statements.—The governors of the Bank of England, at their regular meeting, made no change in the bank's minimum rate for discount, and it remains at 4 per cent. During the week, the bank gained £569,000 bullion, and the proportion of its reserve to its liabilities was raised from 35¾ to 39¾ per cent, against 44⅛ per cent at this date last year. June 14th, the bank made a further gain of £170,000 bullion on balance. The weekly statement of the Bank of France shows losses of 3,400,000 francs gold, and 675,000 francs silver.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, June 15.

The Board of Managers of the Metal Exchange has adopted floor rules, to take effect on June 25th, providing for a daily call at eleven o'clock A.M.

American Pig.—On Monday, American Pig opened weak at prices quoted last Saturday, $20 for No. 1, and $19 for No. 2, standard brands; but during the week there has been a large turn-over, and the leading Lehigh brands are held firm at $22 for No. 1, and $20 for No. 2, although there are some outside makes that are still quoted at lower prices. Forge has been fairly active at the range of $17.50@$18.50. Bessemer is unchanged in price.

Scotch Pig.—The market is still very dull, prices for American being far below the importing point, and arrivals have been going into store to a considerable extent. Warrants are cabled to-day at the Exchange 47s. 1d. On June 13th, the Glasgow quotations received at the Exchange were: Coltness, 61s. 6d.; Langloan, 61s.; Summerlee, 59s. 6d.; Gartsherrie, 57s. 9d.; Glengarnock, 58s. 9d.; and Eglinton, 47s. 9d.

Rails.—Steel rails have ranged from $37.50 for large lots of heavy sections to $40 for light. The consumptive demand continues good, although no very large orders are placed. The quotations to-day are $37@$38. England cables, £4 12s. 6d.@£4 15s. f. o. b.

Old Rails.—Old rails have again been dull except for a lot of 8000 tons sold by the New York, Ontario & Western Railroad, to go to Pittsburg, at $22.50 delivered there. This price is net to the sellers, the buyers paying the small brokerage, said to be $100 for the lot. Other small lots, aggregating about 350 tons, have been sold at $22.50, Jersey City.

Scrap continues nominal at prices quoted last Saturday, $23.50@$24. There is no business doing.

Philadelphia. June 14.

This week's sales of pig-iron do not foot up very largely. Standard brands are developing a little unexpected firmness, because of some quiet selling that has been going on for future delivery. A good deal of inferior iron is offered, but not much is selling; offers of 500 to 1000-ton lots continue to be made. Quotations are weak all around, except in the case of standard and special brands, concerning which makers refuse to make concessions. To-day's prices are for No. 1 at shipping port, $20@$21. Good iron can be had at $20. An effort is making by some holders to adhere to $21. The panicky feeling which prevailed last week has partly blown over, and several prominent makers have announced that, if they can not have better prices, they will hold on until the weak holders have got out of the way. No. 2 Foundry iron is selling at from $19@$20, with $17.50 at furnace as inside figures, and numerous offerings. Forge iron is selling more freely than any other, owing to the continued demand for finished iron and the low prices prevailing. The lowest prices heard of are $17 at furnace, or shipping port prices, $18@$19. Large lots continue to be offered, but there are few takers. Prices have undoubtedly reached the lowest limits, but consumers feel that it is safe to continue the policy of hand-to-mouth buying for a little while longer. Bessemer iron is to be had at $21; very few sales are heard of. Spiegeleisen can be had at $31; several inquiries are floating around.

Muck Bars are in moderate supply at $34@$34.50; and last week's reported sales foot up about 1000 tons for prompt and future delivery.

Blooms.—Several small sales of Charcoal Blooms took place at figures varying from $58@$61. Prices have been improved recently by the restriction of output. Sales of Anthracite Blooms have been heard of from $50@$53.

Manufactured Iron.—A little weakness has been developed within the past few days, though the best makes are held firmly at 2·20c. at mill. Store deliveries are large, and 2·25@$2·30c. is had in most cases. Some of the mills are short of business, and a more active competition is developed, which results in offers of 2·10@2·15c. for good iron. More or less business is coming to hand in country mills, and common iron is booked at 1·90@2c.

Nails.—A large demand continues for nails, and prices are firm at $3@$3.10.

Plate and Tank Iron.—Plate and Tank Iron are active in small lots at 2·40c. for Angles; 3⅛c. for Beams and Channels. Structural iron shows no additional activity, though there is no falling off in the work at mills.

Steel Rails.—This week's business is restricted mostly to small lots, though there are inquiries for large lots, and offers of $37.50.

Old Rails are scarcely heard of. Occasional offerings are made at $22.50 for shipments. Double Heads are nominal. Scrap-iron sells in small lots at $23@$25. Cast, $17@$18, and offers of cargo at $24.

Pittsburg. June 14.

Pig-Iron.—Numerous indications point to a suspension of iron-making in a good many of the mills, ostensibly for the purpose of repairs, but in reality to wait for orders. The effect of the recent signing is now developed in this way, that large consumers are waiting for lower prices, because of the assurances given during May that, without a restriction of production, prices would decline. They are now looking for that decline. The consumption of iron has not increased, and will not, unless consumers are satisfied that lowest prices have been reached. Several furnaces have recently blown out, and this helps the trade. Forge iron is offered at $17@$18, and Foundry at $19.50@$21. Most of the sales are in from 50 to 300-ton lots; 1000-ton lots of Forge have been asked for, but current prices will not be paid, consumers preferring to buy from hand to mouth, rather than risk heavy purchases. Bessemer iron sells in small lots at $21.50; for large lots, $21 is offered. Consumers of crude iron are looking for weak holders, and are occasionally finding them. One thousand tons of Muck Bar in small lots sold at $34@$34.50. Merchant Bar is selling at 2c., but buyers are holding off for 1·80c. and 1·90c. rates. There is a feeling of apprehension that the threat of weakening prices is made with good reason. Nails are in active demand at $3@$3.10 in car-load lots, 60 days. Stocks in first hands are very low, and orders for assorted are filled with difficulty. Steel rails are quoted at $39@$40, but business is done at less. The declining tendency is at work, but mills here will not be the first to sell below current rates. The general situation is quite satisfactory. The steel mills continue to make a full output. The smaller manufacturing establishments are nearly all busily engaged.

The coke trade is endeavoring to escape from the toils of over-production through organized action. The demand for iron through the oil country is steady. The receipts of scrap-iron and old rails are barely sufficient to meet requirements. Boiler-works, bridge-works, locomotive-works, and the large machine-shops have not reduced their force of hands or the volume of work turned out.

METALS.

NEW YORK, Friday Evening, June 15.

Copper.—On further inquiry, we hear that the sale of Lake Copper referred to in our last week's report, of 20,000,000 pounds, was made to manufacturers only. The price paid is understood to have been 15c. without cask, on the dock, the sellers binding themselves not to sell another pound to consumers under 16c. until November 1st, next, while they are at liberty to sell for export at any price they choose in the mean time. Since then the market has been quiet at 15@15½c. for Lake, and 14@15c. for other brands. By cable, we hear from London that copper there is steadier; Best Selected, £69@£70, and Chili Bars £63 15s.@£64 5s. We hear from Liverpool that large quantities of argentiferous copper ores and matte from Montana arrive there all the time. Of the former a contract was completed recently for about 6000 tons, delivery to be spread over twelve months; and parties were in treaty early this month for a further 2000 to 3000 tons. Large sales have also been made of matte from Montana, 280 tons selling toward the close of May for immediate shipment from here at a very full price. It is added that the course of the copper market in England depends almost entirely upon the supplies that may be received from this country. Prices over there are for the moment upheld by speculation. Whether these speculators are financially strong enough to continue doing so for some time longer in the face of amounts yet to come forward from the United States, the next few weeks will show. As for the Chilian export to Europe, it has been light enough, from January 1st to May 27th, 18,878 tons, against 19,357 last year. Spanish exportation for the first quarter has been 148,059 tons of copper ore, against last year 147,078, and 5954 tons of ingot copper, against 6120 in 1882.

Messrs. Richardson & Co., of Swansea, quote, under date of June 1st, ores and regulus 12s.@12s. 7½d. per unit.

The private sales at Swansea during the month of May consist of 382 tons of Concordia ore at 12s.; 435 tons of Bolivian ore at 12s.; 500 tons of New Quebrada Yellow ore at 12s.; 1179 tons ruby ore and 936 tons regulus at 12s. 3d.; 1086 tons of Libiola ore at 12s.; 54 tons of Mount Perry at 12s., and 20 tons at 12s. 4½d.; 105 tons of Moonta ore at 12s. 3d.; 750 tons of Cueva de la Mora precipitate at 12s. 6d.; 18 tons of Aljustrel at 12s. 3d.; 506 tons of Chili regulus at 12s. 6d.; 1100 tons of Cape ore at 12s. 4½d.; and 954 tons of Rio Tinto regulus at 12s. 6d.

Messrs. James & Shakespeare, Liverpool and London, have published the following statistics of copper in England and France, including metal afloat on May 31st:

		May 1 to 31. Imports. Tons.	May 1 to 31. Deliveries. Tons.	
Fine foreign, chiefly Australian		1,126	1,177	London.
Chili.	Bars and ingots	1,748	1,935	Liverpool and Swansea.
	In ores and regulus	1,108	1,250	
Precipitate and sundries		2,496	3,445	
Totals, England		6,478	7,807	
Fine foreign, chiefly American		460	430	France.
Chili bars, ingots, and Barilla		993	1,361	
		7,931	9,598	

	Stocks. May 31. Tons.	May 15. Tons.	April 30. Tons.	
Fine foreign, chiefly Australian	4,215	4,458	4,266	London.
Chili. Bars and ingots	24,734	24,976	24,921	Liverpool and Swansea.
Chili. In ores and regulus	1,813	2,040	1,955	
Precipitate and sundries	3,288	4,475	4,237	
Totals, England	34,050	35,949	35,379	
Fine foreign, chiefly American	140	110	110	France.
Chili bars, ingots, and Barilla	2,012	2,092	2,380	
	36,202	38,151	37,869	
Advised by mail and telegram: Chili	9,158	9,770	9,719	
Australian	1,650	1,650	1,950	
	47,010	49,571	49,538	

		Jan. 1 to May 31. 1883. Tons.	1882. Tons.	1881. Tons.
Imports	Chili	17,884	16,881	14,099
	Other foreign	17,415	14,166	14,705
		35,299	31,047	28,804
Deliveries	Chili	16,807	19,018	17,930
	Other foreign	17,417	13,228	12,079
		34,224	32,246	30,009

Tin has gone on weakening in our market. The market has ruled somewhat more active at a lower range of prices. Transactions for forward delivery have occurred at 21c. for cash. In large lines, spot, we quote 20¾@20⅞c. nominally. London has declined to £94, spot. Singapore cables £95 10s., cost and freight to New York. The Straits exported to England and America during the first five months, 6110 tons of tin, against 5100 tons same time last year.

Lead.—Sales have been made during the week of 300 tons Aurora corroding at 4·42½c., and 300 tons Common at the same price; subsequently, 200 tons corroding sold at 4·45c. We quote both 4·40@4·50c. at the close, on a firm but dull market. There is a good demand for common lead, deliverable in July, August, and September, consumers being anxious to secure a supply for the opening of the campaign; for current requirements, they are sufficiently stocked. Holders meanwhile show little inclination to meet the views of buyers for the months named, and in this manner little occurs for the present. At any rate, the impression is, that at about current figures lead is safe enough for some six weeks to come. London cables a weak market, at £12 15s.@£13 for English pig. Spain exported, during the first quarter, 29,534 tons of pig-lead, against 28,527 in 1882, and 25,370 in 1881.

Messrs. Everett & Post, of Chicago, send us the following dispatch to-day:

Our market is firmer. Sales are reported of 1000 tons Common at 4·15c., and of 700 tons Refined at 4·20c. The market closed strong at 4·20c.

Messrs. John Wahl & Co., of St. Louis, wire us as follows to-day:

Our market is firm. Sales for the week are over 450 tons of Refined at 4·13c., and 70 tons of Hard lead at 4·10c. Sales to-day are 140 tons of Refined at 4·15c.; 150 tons of Chemical at 4·12½c.; and 500 tons of Refined, July delivery, at 4·18c.

Spelter is featureless; very small transactions at 4·60@4·70c. in small lots, Common Domestic, while Silesian is nominally worth 5⅛c. Meanwhile a firmer market is reported by cable from London, where ordinary, at shipping ports, is worth £15@£15 5s. Spanish Calamine exportation during the first quarter has been 4802 tons, against 8616 in 1882, and 2091 in 1881.

Antimony is dull at 10⅝c. for Cookson's, and 9⅝c. for Hallett's. On June 1st, French Star Regulus was worth in the London market £39@£40 per ton.

Quicksilver.—We perceive that the export from Spain has fallen off considerably during the first quarter, being only 185 tons, against 520 tons last year same time, and 698 in 1881.

COAL TRADE REVIEW.

Anthracite.

NEW YORK, Friday Evening, June 15.

There are no new developments since our last issue, nor any improvement in the general condition of the trade. The anthracite trade at present is a puzzle to the most intelligent observer. The sanguine lay much stress upon the fact that the output at the present time is practically 1,500,000 tons ahead of last year, and that the requirements for the rest of the year will be as great as for the corresponding period last year, which would bring the total tonnage for 1883 to 30,000,000 tons or over. It seems to be a fact, also, that the large companies are maintaining prices, while the choicer Lehighs and special brands of coal are handled at circular rates without any difficulty. Outside of these, however, large quantities of coal are offered at prices that are more a matter of barter. Notwithstanding these favorable factors, buyers remain apathetic. There is no snap in the trade. The demand for manufacturing purposes is largely abridged, while dealers do not seem disposed to lay on freely, notwithstanding the threatened advance on the 1st of July, which, as far as we can learn, has not yet been definitely decided upon. In our judgment, there is nothing in the present condition of the market to warrant an advance. We apprehend it would slacken rather than stimulate sales; the only probable effect would be to move coal sold at previous figures. By an ill-advised advance, the months of July and August may be made very quiet months for new business. While we recognize the fact that in the near future anthracite will be in a position to be sold arbitrarily, that day is not yet. The time is coming when it will be used only for domestic purposes, and the demand for coarser uses supplied by the practically inexhaustible quantity of bituminous. The present intense rivalry between the different contending soft coal-fields for trade, and their ability to put coal in the market at very low figures, as shown by some of the recent contracts, admonishes anthracite not to rear its head too high at present on the manufacturing sizes, or it will open the way for its active competitor to slip in and supplant it largely.

Since the above was put in type, we learn that the companies are in consultation upon the subject of an advance, and have set the figures at 10c. on broken, 15c. on egg, and 25c. on stove and chestnut. We can not learn, however, that a definite conclusion has been arrived at.

BITUMINOUS.

In bituminous, there is very little current business doing, although last week witnessed the award of the last remaining contract of importance in New England, the Boston & Maine purchase of fifty thousand tons having been divided between the Consolidation Coal Company and the Elk Garden District. It is reported that the price made was an extremely low one, so low as to justify the report that has been for some time current that the Baltimore & Ohio Railroad has finally recognized the necessity of a cut, private or otherwise, in its rates. It is evident that the future of the bituminous interests, for some time at least, will witness a continued, if not increasing, competition, and that the carriers of this coal must accept the inevitable conclusion that the day of high freight rates is passed. At this juncture, it becomes of interest to anticipate what course will be adopted by the Chesapeake & Ohio Canal Company. The confidence with which those in charge of that work started out at the first of the season with unnecessarily high charges must soon give place, if all signs do not fail, to serious doubts as to whether that work can survive the present and coming competition. It is clear, at this time, that important reductions must be made in the cost of transporting coal via this outlet. At a meeting of the Board of Directors of the Chesapeake & Ohio Canal Company, held in Baltimore on the 13th inst., it was determined to make a present reduction in the canal tolls of ten cents per ton, or from fifty to forty cents, including the charge for wharfage at Cumberland, for which a charge of four cents is now made, leaving the net tolls thirty-six cents per ton. While the reduction now made can not be said to be of any importance, it is at least agreeable to note that the Canal Company has abandoned the attempt to compel the trade to pay a charge for the use of the outlet lock at Georgetown, whether it was used by shippers or not.

The Cumberland District seems to be in the least favorable position of any of the competing interests in the existing and coming strife for trade. With the Pennsylvania Railroad on the north and the Chesapeake & Ohio Railroad on the south, fully awake to the demands and necessities of the trade, and reaching more favored points at tide-water than either the Baltimore & Ohio Railroad or the Chesapeake & Ohio Canal, it would appear that, without some heroic action on the part of the carriers from that district, its business must continue to decline. Already the Delaware River, New York Harbor, the Hudson River, and three fourths of New England have been appropriated by other districts, and the prevailing competition is closely contesting the limited area to which the trade of this region is now restricted.

Vessels have been extremely scarce at all shipping points and freights have advanced.

Horsford's Acid Phosphate.

A Valuable Nerve Tonic.

DR. C. C. OLMSTEAD, Milwaukee, Wis., says: "I have used it in my practice ten years, and consider it a valuable nerve tonic."

For Sale.

150 volumes in German on mining engineering, all new and handsomely bound. Will be sold at less than cost in Germany. Send for Catalogue.

THE arbitration tribunal appointed under the Wallace act to decide the questions at issue between the operators and the miners in the railroad pits of the Pittsburg District is making very slow progress. Committees have been appointed to look into the condition both of the lake trade and of the local trade, and have reported after considerable delay. The facts, whatever they may have been, do not appear to have carried conviction to the minds of either party as to the fallacy of their position ; and after a number of fruitless meetings, the umpire, Mr. JOHN R. MCCUNE, President of the Union National Bank of Pittsburg, has been called upon to decide the question of wages. It will be remembered that the pits are now working under a temporary arrangement, pending the decision, and that, according to the Wallace act, it is not binding on either party so far as questions of wages are concerned. Whatever may be the ruling of the umpire, it is to be hoped that it will be accepted in good faith, and that no complications will arise from a refusal of either party to abide by it.

THE rapid improvement in the methods of manufacturing steel, notably in the open-hearth, and the growing quantity produced in this country, are beginning to tell on the old established iron manufacture. At the present day, quality for quality, steel for many structural and merchant purposes is cheaper than iron, and after some hesitation, always experienced in the introduction of any thing that is new, consumers are taking hold vigorously. The competition is most keenly felt by the makers of special brands of wrought-iron, and has had the effect to a notable extent to lower the quality of the wrought-iron. In their efforts to meet a steadily declining market, makers of special brands have been found to relax in the choice of their raw materials, and to save as much as possible in manipulation. Quality, of course, has suffered under such a system, the temptation to avoid losses and to hold ground so long absolutely under their sway being too great, in many cases, especially as many consumers have unbounded confidence, and do not stop to investigate. We do not believe that such a system can long be continued with impunity.

DURING the past few years, large consumers of rolled iron and steel have begun more and more generally to devote their attention toward providing facilities for themselves manufacturing the cruder forms of iron and steel. The growth in the demand for all kinds of railroad and agricultural machinery has developed manufacturing establishments of great magnitude in the Eastern and Western States. Beginning with ordering special shapes of cast or rolled metal in small quantities, they have grown as consumers, until, to-day, when reasonably busy, they call for very large quantities of material. They have now begun to invest surplus capital in the building of plant for the manufacturing of their own special shapes from cruder material, which they have no trouble in getting in the open market. Their avowed purpose in putting up rolling-mills and foundries of their own is not so much themselves to pocket the profit which those made from whom they bought. They are actuated chiefly by other considerations, the principal being that, having sole control of the preliminary stages of manufacture, they can better make just what they want, are in a better condition to adapt themselves more promptly to changes in their requirements, and can avoid delays and annoyances incident to their dealings with parties whose interests are not always in harmony with their own. It gives them, they claim, a fuller and more absolute control over the quality of their raw material, and hence allows them to place their finished goods in the hands of their customers with more confidence. Of course, only the very largest concerns are in a position to follow such a policy, as it is possible only when the quantities required in the course of manufacture are such as to give regular employment to a special plant. There are indications that this movement will go even farther, and lead to the building of open-hearth furnaces, etc. The advantages which it offers are undoubtedly great, without reference to any saving in the cost, which we believe is entirely problematical. Comparatively, such works must always be restricted in character, and can not command raw material and facilities as cheaply, nor can they gather and hold permanently a large force of skilled workmen, foremen, and engineers.

CORRESPONDENCE.

The Future of Pyrites Mining on the Eastern Sea-Board.

EDITOR ENGINEERING AND MINING JOURNAL :

SIR : Of the manufacturers or those most interested in the question of cheap sulphuric acid in the United States, comparatively few have as yet studied closely or realize fully the importance of the problem now working out by the miners or producers of pyrites.

In an article published by you nearly three years ago, I gave some figures to prove the value of pyrites in comparison with brimstone. It is well known that prices of brimstone in cargo lots have varied but little during that period, yet the wholesale price of commercial acid has changed about 100 per cent. So radical a drop in selling rates can not be accounted for by the lessening of expenses or increased production from like quantities of crude materials ; but a reason can perhaps be found in the erection of surplus chambers to supply the active trade of the years 1881-82 ; and such increase in capacity could only result in a check later on, when the supply was greater than the demand. In seasons of depression, the small firms lower prices, in order to retain trade ; but, unlike former struggles of this kind, the markets are held in the firm grasp of a new class of producers, who claim to be able to make full profits even at this reduced price. These new parties are becoming prominent leaders, from the fact of their ready acquiescence in the manifest destiny of sulphuric acid manufacture from pyrites ores mined in this country. Three years ago, but one or two firms were using pyrites in small quantities, whereas, at the present writing, ores are burned as follows :

Bergenport, N. J., about.....	60 tons.	New Bedford, Mass.....	5 tons.
Newtown Creek, N. Y., about.	65 "	Boston and vicinity, Mass.....	20 "
Bridgeport, Conn....	10 "	Elsewhere.....	10 "
Elizabeth, N. J.....	30 "	Total daily consumption.....	200 tons

There is, of course, a reason for the very slow growth of an industry promising such margins of profit ; but whatever the cause in the past, the fact must now be recognized that acid can not be made from brimstone and sold at present prices ; and further, that manufacturers must meet

Digitized by Google

future trade on about the same basis, to do which pyrites alone can be used.

The difference in cost of sulphur from both sources will make this statement more forcible, namely :

Brimstone (98 per cent sulphur) is selling for.....	$28.00
Pyrites, 2 tons (4480 pounds) cost delivered in New York, say 13 cents per unit of sulphur, or 4480 pounds pyrites (48 per cent sulphur) @ $6.25	= 12.50
In favor of pyrites	$15.50

Produce :

2 tons pyrites, 4480 pounds (48 per cent sulphur).....	= 2150 pounds sulphur
Waste, cinders, etc., 5 per cent..	108 pounds.....2042 pounds net.
1 ton brimstone (98 per cent).....	= 1960 pounds sulphur
Waste, ash, etc., 2 per cent.....	39 pounds.....1921 "
Balance of sulphur in favor of pyrites..	121 " "

Nearly enough to cover difference in cost of working pyrites.

It is easy to see why the present consumers of ores can run their plant to fullest capacity while brimstone-burners are complaining of dull times and slow sales ; and the sooner the trade settles down to these facts, the better for it.

The principal demand for surplus low-grade acids (the making of which justifies large acid plant) has been and will continue to be, for manufacture of superphosphates, the bulk of which is sold south of Baltimore. So wide has been the price of acid made from brimstone here and from pyrites abroad that, annually, tens of thousands of tons of rock phosphate have been sent to Europe for treatment, and then returned to us for use on our exhausted soils. The freight alone on this double shipment is all the profit our agricultural people should be made to pay ; and the strange fact remains that, midway between the sections of greatest production in acids and greatest consumption in superphosphates, there are deposits of the choicest pyrites ever found in quantities, so pure as to rival brimstone in acid-making properties, yet utilized to a very limited extent.

It would be safe to say that ores from these deposits in Virginia can be laid down in every city from New York southward at prices which will guarantee commercial acid (66° B.) at one cent per pound from this time on, and this reduction should affect the price of superphosphates at least thirty per cent from established rates. Assuming that 250,000 tons of fertilizers are consumed annually, costing to average forty dollars per ton, this saving, which should go to farmers, would be so enormous as to double the consumption in a short time, and as a result larger chamber capacity would be required than now used. The increase naturally would be placed nearer to consumers, thus shifting the balance of trade southward. The outlook for the acid trade is certainly encouraging ; but pyrites must from henceforth be the material for its manufacture. What has heretofore been a side issue in our mining industries will now come to the front in such grand proportions as to astonish people unacquainted with the productions of European mines.

Should the manufacturers combine, becoming owners of the pyrites deposits, as is the case with the Rio Tinto and Tharsis mines, there will be seen in this country products exceeding those famous properties, and that within a few years. The fertilizer trade of the South would alone warrant such development, outside of the increasing demands of our country generally. So rapidly is the public becoming awakened to a realization of this new but permanent industry in mining that the change will be upon us before we are aware, and a mineral product will be added to the natural wealth of the Eastern slope, rivaling the mine products of the West. Even Europe can be supplied with pyrites at less rates than paid for Spanish ores ; and with the large working of such deposits along our sea-board, a new impetus will be given to trade channels into which sulphuric acid enters.

Connected with this commencement of operations, will be found the usual crop of "prospects" offered by irresponsible parties, and would-be purchasers should remember that over all the world's surface there are but very few paying deposits yet opened ; and from the peculiar nature of the ores, there can not be found any great number of mines, with quality of mineral, and proper location for shipment.

There are so many drawbacks connected with the securing of these attributes that more than careful examinations should be made of all details, to avoid the inevitable loss that attends mining ventures carelessly entered into.

The problem of placing our Eastern sea-board in the lead for pyrites mining will be, however, the work of but a short time, with the activity usually displayed in our enterprises, and to careful men with large capital the promised reward is beyond precedent. W. H. A.

Dredging for Gold.

EDITOR ENGINEERING AND MINING JOURNAL :

SIR : I have been favored with a copy of a prospectus issued by a company which proposes the use of a new dredging system for working auriferous river sands. As regards the apparatus itself, it may be briefly described as a suction-pump actuated by a vacuum produced in a large vessel supplied with steam from a small boiler. The sandy silt, etc., from the river bottom are intermittently raised through a draught-pipe into the vacuum-chamber, and are thence discharged into a sluice-box supported upon the scow which carries the dredging apparatus. As a means of dredging, pure and simple, there is no reason why this system should not work ; and I believe that experiments have shown that it is capable of handling considerable quantities of material. How the results compare with those of the ordinary dredging-machines, I can not say.

But the main object of this invention is apparently the recovery of gold from Southern river-beds. I quote from the circular of the company :

"From the time of the discovery of gold in California to the present day, mining in this country has developed into such gigantic proportions that it seems to have already outstripped the most visionary expectations of the early Spaniards, and the methods of mining, in their variety, immensity, and ingenuity, have followed closely in its wake, and have only been equaled by the circumstances calling them forth. Of the gold produced, it is estimated that 75 per cent has been obtained from river-beds and gravel-banks, and the means used to save the gold contained in this sand or gravel have varied from the primitive mining-pan of early days to the most elaborate system of sluices, riffles, blankets, and the amalgamated copper and silver plates of to-day. A great many streams admitted to be rich in gold-bearing deposits are abandoned because of the outlay necessary to dam them and make their beds accessible, and the fact that heavy rains and melting snows so frequently produce freshets that sweep away all that presents any obstacle to their headlong course. To obviate these difficulties, and make 'river mining' a practical and comparatively inexpensive enterprise," etc.

Schemes of this kind are an old story on the Pacific coast, having been tried in almost every possible variety during the early period of wild experimentation. Dredgers of different kinds, driven by steam and otherwise, were tested in the Sacramento, San Joaquin, Feather, and American rivers and their tributaries, in every case proving absolute failures. At the time of the excitement about the supposed bonanza at Gold Bluffs, on the sea-coast, a steam dredger was made and sent up from San Francisco to this locality, with the view of working the ocean sands.

Now it is a remarkable fact that, in almost every case where the dredging-machine was tried, the actual presence of gold was a fully determined fact ; and in some instances, dredging failed in places where other methods working side by side were successful. The whole matter was given a full and fair trial in California, and the plan has been emphatically condemned. As a Californian, I can say that the man who should attempt to revive the system of dredging for gold in our State would simply be regarded as being deficient in experience ; and any attempt to raise money for a further trial would be met with derision. In California, the principles of mining for the precious metals and for extracting them are now clearly understood, and resolve themselves into a few simple but hard facts. It is in the Southern States, where gold mining has been practiced on a small scale since the beginning of the century, and where presumably the people ought to know something about it by this time, that most of the visionary and exploded schemes are tried ; the only other field being in mines of the far West managed by people who have no practical knowledge of the subject. (I refer to the class popularly known as the "tender-foot.")

The principal reason why dredging for auriferous sands is not a profitable occupation lies in the nature of the occurrence of gold in river-bottoms. The river-bed acts as a sort of natural ground-sluice, and collects the gold in positions which are not accessible to a dredging apparatus. The misconception upon which similar schemes are founded is, that gold is disseminated regularly through the sand and silt of the river-bottom, so that the question is simply one of raising these materials above the surface. As a matter of fact, the gold particles betake themselves, with characteristic cunning, to all the crevices and out-of-the-way places in which they can hide. Hence, if the bed-rock of a gold placer consists of soft decomposed rock, or of slates, or of schists tilted at a high angle, gold is found permeating it to a considerable distance. In cleaning up the bed of every creek from which the water has been diverted, the gold, even if very finely disseminated, is found in pockets or crevices. An experienced miner at a glance detects the likely spots, and works accordingly. Now if the dredging-machine, instead of lifting all the light, loose, and comparatively barren *detritus* of a river, could get at the right places, and coax the gold from its retirement, the scheme would be a very pretty one. I am supposing that the Southern river-beds, particularly some of those in Georgia, really do contain workable quantities of gold. So much exaggeration always accompanies reports from this region that one needs to heavily discount any statement as to the tenor of these sands. It is a very simple proposition, and one which has been thoroughly established in practice, that if the river-bed is poor, it will not pay to work by any method ; and if it is rich enough to pay for damming, fluming, etc., there is no mystery about the means of working.

I recently read a very glowing account of some Georgia mines in one of the daily papers. The enthusiastic correspondent by whom this was written, among other statements, said that the Georgia gold-fields are "the richest in the United States ;" a remark which seems a little "off," in view of the fact that fifteen States and territories outrank Georgia in point of annual production, and that Georgia furnishes less than one per cent of the total annual gold product of the country. Another statement made by this correspondent was, that English capitalists had paid 5,000,000 for a tract of land in Georgia "guaranteed to contain a gold mine." Still another was, that the ores of this particular locality are "the richest known, but so impregnated with sulphur as to be impracticable for mining." This latter difficulty, however, it is proposed to obviate by a process of which the only description is contained in the following words, which I quote : "By means of electricity and silver cloths, of desulphurizing gold ores to a fine assay."

This, of course, is simply idiotic. There is, on the other hand, nothing apparently absurd about the plan of dredging for gold ; indeed, at one time it occupied the attention of many practical and intelligent miners. It is always a most promising method to those who are ignorant of its history. There is only one difficulty connected with it—it has never been known to pay in the past ; it does not pay now ; and the chances are, that it never will pay. A. W.

NEW YORK, June 11.

THE CRUSHER CONTEST.—On the 30th of May, a public trial was had at Meriden, Conn., between the Gates and the Marsden-Blake crusher. The committee having charge of the contest was composed as follows : W. W. Wright, of the Bradley & Hubbard manufactory, Meriden ; P. Callanan, a contractor of South Bethlehem, N. Y. ; J. S. Lane, road-master of the Hartford division of the New York, New Haven & Hartford Railroad ; Simon Ingersoll, President of the Ingersoll Manufacturing Company, Stamford, Conn. ; Isaac Skidgell, official boiler inspector of Meriden. After the contest, the committee met and signed the following report, dated Meriden, Conn., May 30th, 1883 : The committee met at the quarry of the Messrs. Carpenter Brothers on the above date, to investigate the merits of a 9 by 14 Gates ore-crusher, and a Blake crusher with Marsden's improvements, 9 by 15. The Gates crusher was first run with the following result : Amount of stone crushed, 9 yards ; time used in crushing, 20¼ minutes. The Blake crusher was then run with the following result : Amount of stone crushed, 9 yards ; time used in crushing, 64½ minutes. The crushers received and discharged the same sized stone, and same kind of stone. The machines were run from the same shaft.

-IRON ORE.

Special Correspondence of the Engineering and Mining Journal.

When a telegram came up from Cleveland, on the first of this month, saying that the iron-masters had signed Mr. Jarrett's scale, and that the strike had miscarried, we lake people had a little celebration in a quiet way. Many of our merchants had laid in stocks during the good times of last year, which it would certainly require good times this year to work off, if Bradstreet's agency and the appearance of several of the assessors' rolls signify any thing; and more than one of these saw in a continued strike the infallible portents of bankruptcy. The revival of general business which has set in since the first of June has given buoyancy to all departments of lake industry, and the probabilities are, that the freer circulation of money which has now set in will prevent the phantoms of wholesale and other creditors from materializing in these parts. The mines are now shipping with some energy, although in not so great volume as last season, when the totals sent from Escanaba, St. Ignace, L'Anse, and Marquette had reached by the first week in June 486,101 tons, as contrasted with 269,604 tons for a like period this year. One reason for this discrepancy is the late opening of navigation; but the more adequate reason is the condition of the iron trade. What tactics the mines will pursue as summer comes on, as yet remains to be seen, the future of our shipping depending largely upon sales from now on. One of the largest producing mines will send down cargoes of hard and soft ores until its contracts with vessel-owners have expired, when it will begin a process of restriction. All in all, however, it is probable that the volume will be in increasing and not decreasing ratio, at least until fall.

But a small fraction of the ore which has been consigned to lower ports is as yet sold, and little if any of it is needed by any of the furnaces. In the case of the Republic, however, it was not to be expected that its product would be held at the mine stock-piles, since its fleet of schooners would thereby remain idle or seek business in wild-cat charters. It may seem strange, in view of the comatose condition of the ore trade, that so large a body of ore is sent below, where it must necessarily be much more available to the tender mercies of a glutted market and furnacemen, who, having failed in their battle with the Amalgamated Association of Iron-Workers, are quite likely to transfer the struggle to a less strategically defended field. Even if it should transpire that Eastern puddlers had been guilty of treachery during the debates with Mr. Jarrett, it will not hinder the mills from making common cause against the producers of ore. It was the manifest intention of the iron-masters to make their skilled workmen and the miners share alike in bearing the burdens of the general depression; but as matters now stand, to pinch the mines is their only resource. It was the hight of foolery for certain metropolitan papers to assert that the workingmen were asked to bear the whole burden of hard times, and the arithmetic by which this "answer" was obtained was as novel as it was stupid. Ruling quotations for standard ores would have knocked such columns of nonsense into "pi." To what comparative extent it was really the intention of the mill-owners to make their workmen and the mines bear the financial strain of the present prices for manufactured products, does not, of course, appear, since there are as yet positively no quotations of ores at all which can be given as standard or the basis of calculations; but it may be safely relied upon that, if the schemes of the mill-owners had not miscarried, it is far from likely that the year would have been unremunerative to them, even on a small volume of business. This much, however, is certain, the mines must prepare to lock horns with the mills; for between them from hence must the shock of contest come.

This will further appear when we remember that in all probability American markets will not be troubled with foreign iron products, least of all, foreign ores. A comparison of the imports for the first four months of 1883 with those of 1882 shows a marked falling off this year—a falling off which is not likely to decrease after the tariff bill comes into play in July. And yet a Lancashire authority states that a movement in rails will set in at that time, although probably in no considerable volume. The facts are, ruling quotations have cut off foreign raw and manufactured iron, except it be in tide-water furnaces and markets, and here the profits are so small that it requires a powerful imagination to discover them. The Eastern manager of the largest of our lake mines recently remarked to your correspondent that, if current prices were maintained, no British pig could find its way as far west as Pittsburg. Taking into account the meager number of furnaces and mills on our Eastern sea-board, it may be safely said that, if things continue as they now are, the American market will be held by American mills and American mines. If there be any comfort in this, our mine operators can roll the morsel under their tongues to their heart's content.

The market for our lake ores, both lean and fat, turns accordingly upon the ancient hinges of supply and demand. Given the demand, and the amount of American ore which can safely be thrown upon the market is easy to be computed. A gentleman who has the very choicest facilities for obtaining the precise facts informed me, in a recent visit to the Peninsula, that not less than 500,000 tons of ore from last year's digging lay unsold or unused on the first of June on the docks of Cleveland alone. One of our mines which is already shipping an enormous block of ore from its winter stock-pile had 50,000 tons in the Cleveland yards, left over from 1882. From what your correspondent learns of the Illinois mills, he is led to infer that they are no worse off than their Eastern competitors. Indeed, so large an amount of ore or its equivalent is on hand in furnace markets that, had a strike been inaugurated on the first of June and continued for three months, it is not likely that a reinforcement of even a hundred thousand tons of ore would have been needed to fill all furnace orders until the opening of navigation in 1884. In the light of this fact, the present course of the mines, in sending down unsold ore, is, to say the least, dubious; for if more ore is piled up in Erie ports than buyers will take, the return of another year will find the ore question no less enigmatical and grave than this spring. As it is, we lake men have to confess that the mill-owners have no reason to be particularly anxious about supplies, and are not surprised, though we are somewhat discomfited, that they are taking things easy as regards making contracts for ore deliveries. One of our mines which had found buyers for over 250,000 tons by the first of March, 1882, has sold less than 30,000 tons thus far, and that in petty lots. The president of one of our great mines said to your correspondent recently, that a large mill had written an offer for a large block of ore at prices which would have been ridiculed last year. After consuming a week in conference with the directors, he mailed an acceptance of the offer, whereupon the furnace-men replied that their offer was not intended to hang fire so long, and that it was withdrawn. Now offers are mere bantering, "obstruction," so as to let the season wear on and the mines become importunate if not impecunious. Up to the first of June, no ore had been sold to speak of, by any or all of the mines. As a consequence, many of them have taken in sail and are "developing" their properties, and not at all rushing them. Your correspondent was astonished, on visiting one of the great Marquette County mines a few days since, to find literally no stoping at all going on. It would be tedious to recite the condition of the individual mines at this writing; but a canvass of them made about the first instant demonstrated the foregoing facts.

Concerning prices for ores, owing to the uncertain and fluctuating character of the market, there is nothing at all to be said in this letter, although I am quite certain that the prices quoted by your Cleveland correspondent were looked at by a microscope—none of us has seen them with the naked eye. Certain it is, that mine-owners will "look at" almost any offers that are not altogether unreasonable, and a few, though only a few, of them may be compelled to look at prices which are beyond reason. As a rule, however, the Marquette and Menominee mines have a splendid backing, and any furnace which calculates, by reason of the depression, to catch them on the hip, may find a Daniel come to judgment, which will turn the scales against the said furnace in vigorous measure. I have not attempted to moralize on the lessons which this prosaical study of the industry suggests, not more to our peninsular people than to the iron-masters in lower towns. These lessons, however, are certainly important, and contain several harbingers of hope; but this, your correspondent modestly thinks, is beyond peradventure: the furnace-men and ore-men ought not to play dog eat dog, but to make common cause for mutual interests, lest in their wrangle they each furnish a cat's-paw by which the English *simiadæ* will help themselves to our American chestnuts. But of this more at another time.

SPECULAR.

ON MINERAL VEIN FORMATION NOW IN PROGRESS AT STEAMBOAT SPRINGS, COMPARED WITH THE SAME AT SULPHUR BANK.*

By Joseph Le Conte.

I recently visited Steamboat Springs for the purpose of comparing the phenomena there exhibited with those previously observed at Sulphur Bank and described in this Journal July last. These springs have already been described by Phillips and Laur.† I shall, therefore, give only such brief description as is necessary to make my comparison intelligible.

The springs are in Washoe County, Nevada, about fifteen miles south of Reno and immediately on the railroad to Carson and Virginia City. The place is, therefore, easily accessible, and, being a health resort, there are good accommodations for visitors. The springs issue in a narrow north and south valley, with volcanic ridges on each side, the vents being mainly on the slope of the western ridge. On nearing the place by cars, the attention of the traveler is strongly attracted by the clouds of condensed steam issuing from many vents over a bare rocky space about the hotel and extending northward a half-mile or more. On closer examination, the vents are seen to be separate, but occurring in linear series, showing that they are connected by continuous fissures. These fissures may be traced from vent to vent often as a vein, filled by a deposit of silica from the hot alkaline waters. The separate vents, especially at the south end of the fumarole area, are each on the top of a gently-sloping mound (some of which are from 15 to 20 feet high) formed by deposit from the water. The mounds, however, run together at their bases and form a continuous crust of silica. Toward the northern part of the area, the crust is still more evenly continuous. It forms here, in fact, a continuous rounded shell-like deposit, firm, hard, and ringing under the heel, about 200 or 300 yards wide, at least a half-mile long, and from 15 to 20 feet in thickness. This clean, hard, shell-like crust lies against the slope of the western hill and reaches to near the bottom of the valley.

We have said that about the hotel the vents are mostly separate but arranged on lines which were evidently fissures. These fissures are some of them open, some partly filled, but water still issuing from a narrow crevice in the middle, some wholly filled with deposit. The deposited silica occurs in almost every conceivable form—most commonly as tufaceous sinter in thin horizontal layers, sometimes with beautiful agate-like structure, sometimes milky chalcedonic, and sometimes saccharoid quartz. Everywhere the horizontal-banded structure is conspicuous, and in some cases the filling of fissures by successive deposits has given rise to a vertical banded structure like that found in veins. This structure, however, was by no means so conspicuous as I had been led to expect from the description of previous observers. The deposits in many places are stained and clouded with metals, especially iron oxide and cinnabar. Wherever the issuance of the hot water is still going on slowly, the silica is found in a gelatinous condition. Other observers have found in small quantities many other metallic sulphides, and even free gold is said to have been found in these sulphides. Here then undoubtedly mineral veins are now forming under our eyes, but their metallic contents are in very small proportion.

In the more northern portion of the fumarole area, as already stated, the crust is more continuous and extensive, and probably thicker. This part was therefore probably at one time the principal seat of fumarolic action, but the active vents are now very few. This whole area is intersected by a system of open parallel fissures of great size and differing somewhat from those already mentioned. They are seven or eight in number, and the five largest are at least half a mile long, a foot wide, about twenty-five feet apart, and apparently from 20 to 30 feet deep. They are tortuous, with rough ragged edges, and evidently reach to the bottom of the crust. Water does not now issue from them, but can be seen and heard seven or eight feet below, in violent agitation from the escape of steam and carbonic acid. There is no evidence that it ever issued from

* A paper read at the Washington Meeting of the National Academy of Sciences. From the American Journal of Science.

Digitized by Google

them; for their sides and edges are sharply jagged like a fracture unmodified by subsequent deposit. The water in them seems to issue lower down to the east and north, where are found active vents and even feeble geyser eruptions which are said to have been more violent at one time than now.

It will be seen then that there are indeed here fissures filled and now filling with quartz veinstone of ribboned structure and containing metallic sulphides, yet these are not fissures and veins in the country-rock, but only in the *crust deposit*. The country-rock is completely buried under this crust, probably from 20 to 30 feet deep, and therefore completely concealed from view. The hot alkaline waters loaded with silica seem to have deposited so abundantly that they cover and choke up their own vents, while other vents are constantly formed by the expansive force of steam fissuring the crust previously formed. The great fissures described above were probably formed in this way, and perhaps opened by a slight bodily sliding of the crust toward the bottom of the valley. The analogy of the filled fissures to the veins is not so complete as I had expected, or as it is at Sulphur Bank. If we could get beneath the crust and find fissures in the country-rock filled by deposit, then indeed the analogy would be complete. This is exactly what we actually find at Sulphur Bank. In the immediate fumarole area, the country-rock is concealed; but wherever not covered by deposit, its character is evident. On the hill slope and in the valley to the very margin of the deposit it is everywhere a quartz-trachyte or rhyolite. Along the crest of the western ridge, however, there is an outburst of black, very basic rock, probably basalt. This ridge is probably a basaltic dike breaking through a rhyolitic country-rock. It is not improbable that the fumaroles are the feeble remnants of a volcanic activity inaugurated by the basaltic outburst.

Cinnabar Mines in the Vicinity.—About a mile to the westward of the springs, cinnabar mines have been opened and reduction-works established. A considerable amount of cinnabar has been taken out, but the work is now abandoned. Here the surface appearances are entirely different from those at Steamboat Springs, and more like those at Sulphur Bank. There is no crust deposit; but, on the contrary, the whole hillside rock is decomposed by acid vapors into a white chalky earth like that at Sulphur Bank, except that in this case the rock being rhyolite, the chalky earth is full of disseminated grains of free quartz. Tunnels have been driven into the hillside at various levels and the ore extracted from the decomposed earthy matter, but the sound rock has not been reached. In this loose earth are found in considerable quantities both cinnabar and sulphur—the former in streaks as if deposited in water-ways, the latter more irregularly and widely distributed, as if formed by oxidation of sulphureted hydrogen gas. In some places, sulphates of iron and alumina are very abundant, even more so than at Sulphur Bank. There can be no doubt, therefore, that there came up, and probably are still coming up, hot waters containing alkaline carbonates and alkaline sulphides, carrying in solution and depositing sulphides of mercury and iron by cooling, and by oxidation depositing also sulphur and forming sulphuric acid. In a word, the phenomena are here very similar to those at Sulphur Bank, except that here the up-coming solfataric waters are less abundant and perhaps less rich in metallic sulphides. This, however, can only be determined with a certainty by deep explorations.

Comparison of Steamboat Springs with Sulphur Bank.—A comparison of the phenomena at these two places is interesting. The surface phenomena, it is seen, are very different; in fact, in complete contrast. At Steamboat Springs, the whole country-rock is covered from 20 to 30 feet deep and completely concealed by a hard crust of deposited silica; at Sulphur Bank, on the contrary, there is no crust but only a soft chalky residue from the acid decomposition of surface rock—a residual silica which from the bases have been all extracted. The reason of the difference is obvious. At Steamboat Springs, the hot waters contain mainly alkaline carbonates carrying silica in solution, while at Sulphur Bank they contain also largely alkaline sulphides and carry metallic sulphides in solution. A crust can not form at Sulphur Bank, because the silica is not brought to the surface, the up-coming alkaline waters carrying silica being neutralized before reaching the surface by the down-going acid waters. The chalky residues of acid decomposition of the surface rocks, so conspicuous at Sulphur Bank, do not occur at Steamboat Springs, because the alkaline sulphides are in too small proportion to produce any conspicuous effects by oxidation; whatever of rock decomposition occurs there, must be alkaline, not acid—by removal of silica, not of bases. Such alkaline decomposition doubtless does occur beneath the crust at Steamboat, as it does at Sulphur Bank below atmospheric influences. Again, since alkaline sulphides are the solvents of metallic sulphides, at Steamboat Springs the deposits are almost pure silica, only stained here and there with metallic oxides and sulphides; while at Sulphur Bank, the metallic sulphides, especially mercuric sulphide, are in large quantity. At the abandoned cinnabar mines near Steamboat Springs, alkaline sulphides carrying metallic sulphides, again occur, but here again also, these are associated with the surface phenomena characteristic of solfataric waters.

At the California Geysers—so-called—we find also solfataric action with its invariable accompaniment of acid decomposition of the surface rocks with earthy residue; but the freight of valuable metallic sulphides seems to be less abundant there, probably only because not met with in the course of the up-coming waters. Iron sulphide, however, is abundantly deposited. In *true* geysers, like those of Yellowstone Park and Iceland, the superheated waters contain usually only alkaline carbonates, and therefore carry in solution and deposit only silica.

Thus, then, we have a connected series of deposits from superheated waters, their characters depending upon the composition of these waters: 1. In true geysers, the waters, being pure alkaline carbonates, deposit only silica. 2. At Steamboat Springs, there are some alkaline sulphides, and therefore some metallic sulphides, but not enough to prevent a crust of deposited silica. 3. At the California Geysers—so-called—solfataric action is conspicuous, and therefore no crust is formed, but only earthy residue of acid decomposition of surface rocks. Here we have also metallic sulphides deposited, but these are of little value. 4. At the cinnabar mines, near Steamboat Springs, we have solfataric waters depositing cinnabar and other metallic sulphides in considerable quantity, but whether in profitable quantity can not be known certainly unless deeper explorations be undertaken. 5. Finally, at Sulphur Bank, the deposit of metallic sulphides is abundant and the formation of metalliferous veins is illustrated in the most perfect manner, on account of the deep explorations undertaken at this place.

In connection with the idea so common, that the metals are derived immediately from igneous rocks, it may be well to draw attention to the fact, that igneous rocks are by far most abundant and igneous action most conspicuous at Yellowstone Geysers and at Steamboat Springs, where there are little or no metals; while at Sulphur Bank, the country-rocks beneath a depth of from 20 to 30 feet are stratified sandstones and shales of Cretaceous age, the igneous rocks being very superficial and evidently contributing nothing to the metalliferous deposits. It would seem that igneous *action* supplies a necessary *condition* (heat) for the formation, rather than that igneous *rocks* supply the *materials* of metalliferous veins.

GOLD MINING IN SOUTH CAROLINA.*

By E. Gybbon Spilsbury.

From time to time, for the last quarter of a century, considerable attention has been called to the gold deposits of North Carolina and Georgia, and much capital has been expended in their development; but the existence of large areas of gold-bearing rocks in the State of South Carolina is known only to a comparatively few. The production of the South Carolina mines, being usually disposed of at the United States branch mint in Charlotte, has been generally credited to the North Carolina or Georgia mines. The mines of Lancaster and Chesterfield counties, South Carolina, have for years been as large producers as any in the neighboring States, and many of them have mint records of yields ranging in the millions. Before the war, most of these deposits were worked in a more or less desultory manner, down to about the water-level, and then stopped; and it is only within the last few years that operations have recommenced in any of them. At the present time, even, there are only four mines of any magnitude operated in the State. These are, the Haile gold mine and the Funderbark mine, in Lancaster County; the Brewer mine, in Chesterfield County; and the West mine, in Union County.

I am aware that the general impression is not favorable to gold mining in the South, owing, doubtless, to the almost general failure of the many companies which have started work in this section. Still, to those who have studied the geology of the country and are acquainted with the auriferous deposits, it will not sound like exaggeration when I say that there is more money to be made to-day in gold mining in the Carolinas and Georgia, with a moderate outlay of capital, than in any equal area in California. The question very naturally arises then, Why, if this is the case, are there not more successes and fewer failures? The answer to this seems to me very plain. Under the old slave *régime*, gold-washing and mining were generally carried on in a very desultory manner and on a small scale, each land-owner just working on his own farm, using his overseer to manage his negroes in the mines as well as on the farm. Thus, both the overseers and negroes gradually obtained more or less knowledge of mining and milling such as they had seen on their neighbors' plantations, and which was of the most rudimentary character. After the war, when the attention of outside capital became attracted to these mines, these people became naturally the miners and foremen of the district. Their shiftless and desultory manner of working, which yielded profit enough to satisfy small individual owners, proved insufficient to grapple with the real difficulties of regular mining and milling, and hence arose the impression that the Southern ores were hard to mine, and harder yet to reduce. This cry was at once responded to by the patent process men, who came in swarms, each to be the deliverer from some terrible difficulty which the extraction of the gold from these ores presented. The process, when completed, would not always work right, and hence the inevitable collapse and general engendering of distrust in the value of the properties. As a fact, however, the average ores of the South present fewer difficulties of treatment than do those of the West, to any one who is at all acquainted with the requirements of the case. For instance, what would be thought in Colorado of a mining engineer who would put up a stamp-mill and amalgamation-works to treat cupriferous pyrites carrying gold? Yet I know of several cases where this has been tried in the South.

Another cause of failure has been the general exaggeration of the values of the ores. As a rule, the surface ores in this section are very rich, owing to a gradual concentration of the gold as the matrix is decomposed by atmospheric influences; whereas the general deposits are of comparatively low-grade ores when once water-level has been attained. Of course, there are exceptions; but this I find to be the general rule.

As the Haile mine is essentially a low-grade mine, and is still one of the largest bullion-producers, if not the largest, of the South, a short description of the mine and system of treatment of the ores may not be out of place.

The mine property, consisting of a tract of some 1900 acres, is situated in the southeastern corner of Lancaster County, South Carolina, about one and a half miles from the Kershaw line. The formation of the country-rock is talcose slate, having a general trend of north 18 degrees east. These talcose schists are tilted up on end, being in places nearly vertical, and nowhere having a dip of over twenty degrees to the northwest. They are throughout very highly impregnated with fine crystals of iron and arsenical sulphides. The beds of auriferous rock seem to follow in general direction the trend of the country-rock. There are at least two distinct mineral belts running in a parallel direction through the property. A series of trap dikes cuts through the slates almost at right angles; and although there appears to be no lateral dislocation caused by these dikes, still they probably bear some intimate relation to the mineralizing of the belts they cross. The main or Haile deposit has been traced over a distance of three miles, and has been worked on for many years, down to a depth of about sixty feet. Its general width may be taken at sixty-five feet. The average value down to the bottom of the present workings, 75 feet from the surface, is about $11 per ton, although bunches of high-grade

* A paper read at the Roanoke Meeting of the American Institute of Mining Engineers

Digitized by Google

ores are sometimes found. The ore is undoubtedly an altered slate, and to an inexperienced eye differs very little from the surrounding country-rock. In reality, however, in composition it is nearer a quartzite than a talcose slate, the magnesia being replaced by silica, and contains in places near the center of the beds over 80 per cent of silica. From this, it gradually diminishes in hardness toward the walls, the foliations become thinner and more marked, interspersed with thin seams of pure quartz, until gradually the soft talcose slate is reached. There is no actual line of demarkation visible, except in a very few places near the surface. The amount of gold also diminishes very gradually, and indeed none of the surrounding slates within a distance of fifty feet on each side of the deposit is without more or less show of gold. From the size of the deposit, of course mining is very cheap, and the introduction of power-drills has brought the cost of extraction down to eighty cents per ton.

Across the valley to the north of this Haile deposit, is another parallel one of almost equal magnitude, known as the "Blauvelt vein," the characteristics of which are very similar. These deposits have been worked from time to time in a desultory manner for the last fifty years, showing, according to the mint returns, a yield of over one and a quarter million dollars. During the fall of 1879, the property was bought by the present company, and the work has been pushed steadily ever since.

The ore is hoisted from the mine up a slope, the same cars taking it down on an elevated tramway to the mill. The mill is an ordinary twenty-stamp, California type, the weight of the stamps being 750 pounds, and the average number of drops 80 per minute. The fall of the stamps is seven inches average. The screens used are forty-mesh. The amount of ore put through daily is from 35 to 37 tons. The average value of the ore is from $11 to $12 per ton. Of this amount, from $3.50 to $4 is free gold, the remainder being combined and more or less inclosed in the sulphides. The mortars are provided with inside plates, which are taken out and cleaned every day, yielding from $75 to $80 per day. Each battery is also provided with ten feet of copper plates outside, the average catch of which is about two thirds more than the inside plates. At the bottom of the plate-tables, I have put in a series of small spitzkasten, with an upward current of water, which I find very effective in catching whatever quicksilver is lost from the plates. All the tailings are then run over concentrators, whereby the sulphurets are saved, the average tailings which finally leave the mill showing less than thirty cents of gold per ton. Our entire cost of milling, including labor, cord-wood, wear and tear of machinery, and labor of concentration, is fifty-one cents per ton, to which should be added two pounds of shoes and dies to the ton of ore, say nine cents, making in all a total cost of 60 cents per ton.

The next process is the roasting of the concentrated sulphides, which, at the Haile mine, do not contain the faintest trace of copper. To effect this thoroughly, was supposed to be a matter presenting great difficulties, and a special furnace was designed to overcome them. This furnace consists of a large coil 450 feet long. of five-inch wrought-iron pipe, built in a suitable furnace, and heated to a low red heat. The finely-divided ore is blown through this pipe with a large excess of air into suitable receiving-chambers. Some of the mechanical details of this furnace are not yet perfected; but the roast made by it when working right is most complete, scarcely the faintest trace of sulphur being left in the ore, and it further has the advantage that, through the constant attrition of the particles of ore among themselves in their passage through the pipes, the gold is entirely freed from all scale, and left perfectly bright and ready for amalgamation. Like all mechanical roasters, however, this furnace can not be relied on for perfectly uniform results; and until this and other mechanical difficulties have been obviated, I have fallen back on the old-fashioned but always reliable "Fortschaufelungs" furnace. Here in the South, where labor is obtainable at 90 cents per day, where wood costs us less than $1 per cord delivered at the furnace, the advantages to be gained by automatic rabbling, in whatever way attained, are so slight that they are much more than counterbalanced by the perfect control one has all the time over the charge roasted in the reverberatory furnace. The advantages of the latter, in the matter of first cost, are of course undeniable. Our double-hearth furnaces, 40 feet long by 5 feet wide, do not cost us over $800 all complete, and have a capacity of from six to ten tons per day of twenty-four hours. Taking an average of eight tons per day, the cost of roasting does not exceed $1.10 per ton.

The roasted ores, after cooling, then go to our amalgamation-works, which, from their economy and success, deserve a special notice. It is, I believe, a well-established fact that the old Freiberg barrel process of amalgamation has always yielded as good if not better results than any other process, the great objection to it being the great length of time required for the thorough amalgamation of the pulp, owing to the difficulty of causing each particle of the gold to come in contact with the metallic mercury, and the consequent excessive flouring of the quicksilver. In order to obviate this, and cause a more thorough dissemination of the mercury through the charge, Mr. Designolle, a well-known French mining engineer, proposed using a solution of the bichloride instead of metallic mercury, at the same time placing in the barrel enough metallic iron to thoroughly effect the decomposition of the bichloride. This he found so thoroughly successful that he designed and patented a complete combination plant for treating ores by this process. At first, he claimed to be able to treat unroasted sulphides directly; but as a general thing, this claim has proved a failure. On the other hand, with roasted ores it has proved itself even more successful than was contemplated at first. The process is as follows: The roasted ore, in charges of 600 pounds each, is put into a cast-iron cylinder or barrel, in which are also placed about 1000 pounds of cast-iron balls. The cylinder is then partially filled with water, and about half a gallon of the bichloride of mercury solution is added. The barrel is then rapidly revolved for five minutes, at the end of which time another half-gallon of the solution is added, and the cylinder again revolved for fifteen minutes. At the end of that time, every particle of gold has been amalgamated, and the barrel is discharged into a large settler, in the concave bottom of which is a bed of metallic mercury. The pulp is kept in suspension in his settler by revolving rakes, which keep the surface of the mercury-bed clean and ready to absorb the particles of amalgam immediately as they settle. The pulp is discharged from this settler in a thin stream over a series of revolving centrifugal copper plates, which catch whatever particles of amalgam may still be held in suspension in it. From the plate machine, the pulp discharges into a second settler similar to the first one, thus finally catching what may have passed through the former settler and the plates. The simplicity of the whole process is remarkable. With our plant, costing in all less than four thousand dollars, including building, we can treat from eighteen to twenty tons per day, with the labor of one man and one boy. The whole cost of treatment at our mill, including chemicals, labor, steam, and wear and tear of machinery, is 38 cents per ton.

Having given a general outline of the manipulation of this process, it may be interesting to look into its chemistry. The composition of the standard solution used is as follows: Mercury bichloride, 1; common salt, 2; muriatic acid, 1. The proportion of the acid may be varied according as the gold in the charge to be treated is more or less rusty. These chemicals are mixed with any reasonable amount of water, with us the latter being in the ratio of 64 gallons to 8 pounds of bichloride, thus giving us one ounce of bichloride to the half-gallon of mixture. For all ores containing under three quarters of an ounce of gold per ton, one gallon of the mixture per charge is fully sufficient, after which half a gallon extra is added for each half-ounce of gold additional. The chemical reaction which takes place is $HgCl_2 + 2Fe = 2FeCl + Hg$. This simple reaction is due to the presence of the chloride of sodium in the mixture. Where this is not present, it is probable that the first reaction would be $HgCl_2 + Fe = HgCl + FeCl$, followed by a secondary reaction of $HgCl + Fe = Hg + FeCl$. It was therefore on the former reaction that Mr. Designolle based his invention. The extreme rapidity, however, with which the amalgamation takes place seems to point to some further action than the above, as we know that the decomposition of mercury bichloride by metallic iron is a comparatively slow process, and that the globules of mercury might revolve for a considerable time in the mass, as in the old Freiberg barrels, without coming in actual contact with the particles of gold. In point of fact, however, it is just this slowness of action which is the chief element of success of the process. Very little if any of the amalgamation, I believe, takes place by the particles of gold coming in contact with globules of free mercury, the secret of the whole success being that when, in the acid water-bath, any particle of the gold comes in contact with the iron, an electrolytic action is at once established, and the deposition of the mercury over the whole surface of the gold is instantaneous. It matters not how minute the portion of the gold exposed to the contact is, the whole of the surface is at once amalgamated. Even gold covered over with rust scales of iron, if exposed on one point only, will become thoroughly amalgamated throughout, the scale breaking loose, leaving the amalgam free. The action is indeed so rapid that, on ore containing $43 per ton showing freely in the pan before treatment, not a trace of unamalgamated gold could be found after the trituration had continued for ten minutes.

A few months since, my attention was called to Professor Egleston's paper on the defects of the stamp-mill, and the assertion made by him of the non-amalgability of hammered gold caused me much astonishment. After a careful series of experiments, I have come to the conclusion that the conditions of the gold under which Professor Egleston made his discovery must differ considerably from the general condition of the gold under the stamps, as in no case could I repeat his experiments with the same results as obtained by him. As the instantaneous amalgamation of gold by contact with iron in the bichloride solution is quite a beautiful sight, I have brought some of our standard solution with me, with some small plates of hammered gold, and as you will see, the instant the iron touches the gold, the mercury spreads like a vail over the entire surface.

COPPER SLIME TREATMENT.*

By F. G. Coggin, Lake Linden, Mich.

"If you could only get that motion into a machine," said a gentleman, as he watched the process of making a "van" on a shovel, and saw the copper roll up to the highest point, "it would beat the world for slime dressing." This idea has led to many an effort to get that peculiar motion, called the "vanning motion;" and so cams, eccentrics, eccentric gears, levers, bell-cranks, toggle-joints, links, springs, etc., have been brought into requisition, while a contribution has been laid upon all the conceivable motions, rolling, tumbling, swinging, jerking, tossing, dropping, tripping, intermittent, regular and irregular, or a combination of some of them, to which have been added percussion, concussion, and more discussion—all in a vain attempt to combine in a single machine the consecutive motions of the shovel, in washing, flowing, and tossing the van. The Patent-Office reports, and the various mills of the country, show, as a result of this, a lot of gimcracks, most of which never went beyond a first trial, finding their way to the scrap-heat. Others still running might as well be there; while some have considerable merit for dressing other and richer sands than copper.

It does look tempting to see that clean edge of copper climbing up the shovel-blade; but those who have seen in it such visions of large fortunes have not considered the time it takes to make a van, compared with the small quantity treated upon the shovel; and this points to the reason for the failure of all that class of machines called "vanning machines," when used for dressing copper slimes, namely, a lack of capacity. The writer has come to this conclusion through an experience with the Rittinger side percussion-table of the most improved make, sent from Germany to the Calumet & Hecla Mining Company, and with the Ellenbecker tables, used by the same company, both of which are good types of that class of machines. In both of these machines, the tables are suspended by rods which allow them to swing, and which can also be

* A paper read at the Roanoke Meeting of the American Institute of Mining Engineers.

Digitized by Google

adjusted for the purpose of varying the inclination of the table. In the Rittinger machine, the motion of the table is at a right angle to the flow of the slime, being produced by a wiper-cam which throws the table against a spring, which throws it quickly back against a stop, the percussion throwing up the mineral. In the Ellenbecker table, the motion is with the flow of the slime, and has a quick return, produced by the use of eccentric gears, the idea of the latter being taken from the valve-gear of the old Ball steam stamp. The estimated capacity of the Rittinger machine was eight tons per twenty-four hours; but it would not properly treat over five tons in that time, or about fifty pounds per square foot of floor space taken up by the machine. The Ellenbecker table has about the same capacity. The assay of slime was about 1·3 per cent; that of the tails, 0·97 per cent. This is not considered very good work.

Of other machines for dressing slimes, the best known are the fixed round buddle, the revolving table, and perhaps the Frue vanner may be included in this class of machines, although having had no experience with the latter, I can say nothing with reference to its capabilities. The principle governing the concentration upon both the former is the same. In the one, the table is fixed while the distributing and washing apparatus revolves. In the other, the table revolves while the rest of the apparatus is fixed. The revolving table is the most largely used in this country, the design of Mr. Evans, of the Atlantic mine, Michigan, being almost exclusively used in the copper mills of Upper Michigan. This differs little from the German revolving table except that it has a "dead-head" at the center from 6 to 8 feet in diameter, one half of which is used for distributing the slime, the other half being used for clear water. The outer rim of the latter is a spiral, the surface broadening toward that point where the concentration is washed off. I have also made this rim in steps of from six to ten inches, with good results.

It may be said that this dead-head takes up a large area from the table; but this area, being immediately around the center of the table, is of little or no value for settlement; for the current of the slime delivered at the center is too rapid for settlement to take place until it has spread itself over an area equal to that of the dead-head, the office of which is to spread the slime moderately and evenly upon the revolving table.

In a paper read before the Institute at its last meeting in Boston, by Mr. R. P. Rothwell, it was stated that in the German dressing-works the revolving tables were being superseded by the Linkenbach fixed round buddle for the apparent reason that the revolving tables, if over 17 feet in diameter, were expensive to build, were unwieldy, and necessitated more operations to concentrate. Some two years ago, a complete set of drawings of the Linkenbach buddle, with a set of irons for the same, were sent to the Calumet & Hecla Mining Company with a view to their introduction, the German estimate of the cost of a single buddle being $717. A thorough examination of the drawings, with their description, and of the irons sent, compared with the practical workings, etc., of the Evans table, led to the adoption of the latter for several reasons:

1. The cost. The Evans table, with only moderate facilities for its construction, will not exceed $225. The fixed buddle, with the inventor's estimate of the material and labor at prices paid for such in this section, would cost at least four times as much, or $900. This, for the number of tables required by the Calumet & Hecla Company to properly dress its slimes, would make a difference in first cost of $20,000.

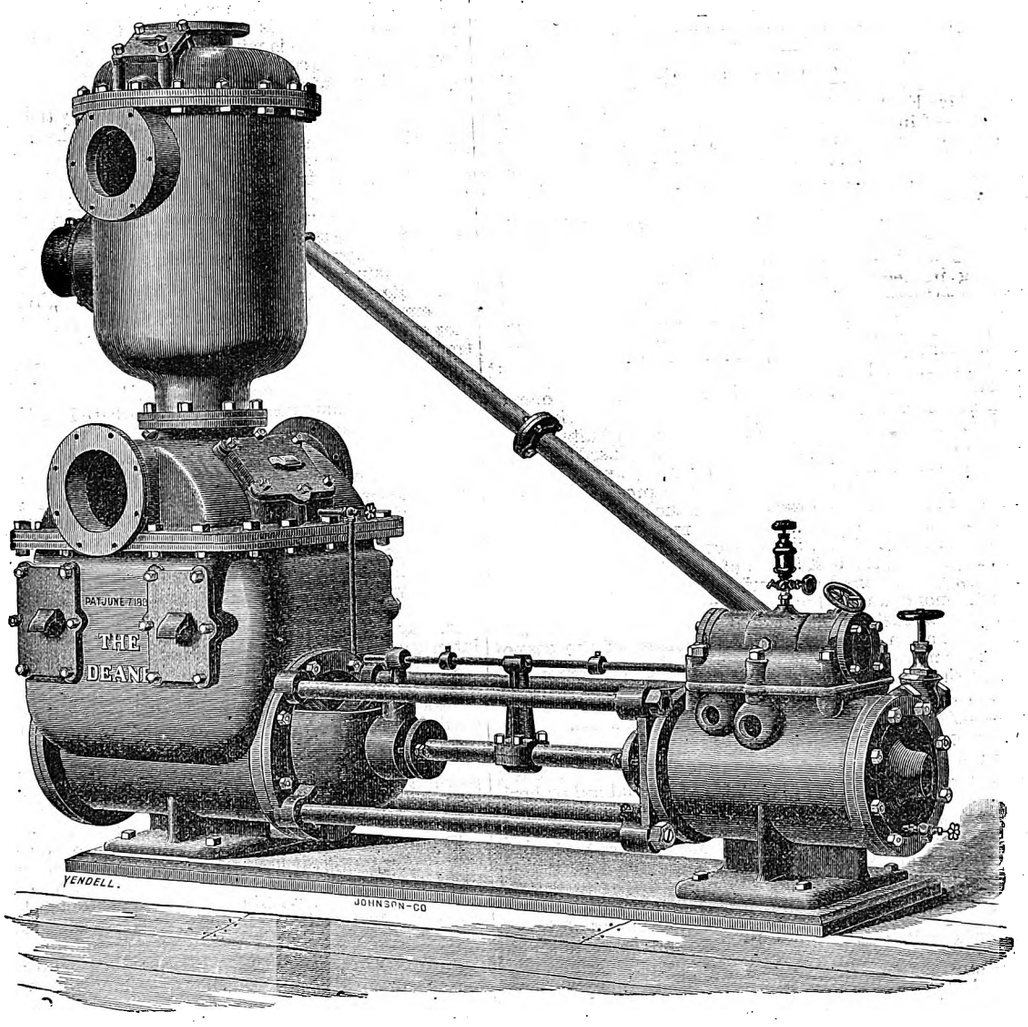
2. The fixed buddle, with its revolving apparatus, is more complicated than the Evans table, and therefore more liable to repairs. If there was any thing to compensate for the extra cost of the fixed buddle, it would not matter; but there does not seem to be any thing. The capacity of the two machines seems to be about alike; that is, from 12 to 15 tons of slime (weighed dry) per twenty-four hours. This refers to a table 20 feet in diameter, as compared with those referred to by Mr. Rothwell, said to be about 26 feet in diameter. Comparing the capacity of the Evans table with that of the Rittinger percussion-table, per square foot of floor space taken up, the former gives 96 pounds of slimes against 50 pounds by the latter, a gain in favor of the Evans table, or round buddle, of 92 per cent. The water required by the buddle and table does not seem to vary much. Taking Mr. Rothwell's figures, the minimum, 5½ tons of slime in ten hours with 19 gallons per minute, gives about 2100 gallons of water to the ton of sand. Experiments with the Evans table give about 2000 gallons to the ton. There is no difficulty in making an Evans table 20 feet in diameter or more without making it unwieldy, and at a cost specified above. Nor is there any difficulty in putting one table above another, either on the same shaft, to be driven together, or on frame-work, to be driven independently; and in either case, the power to drive them is of no consequence, as the table revolves upon a steel step 1¼ inches in diameter, and a child could turn one even while loaded. With respect to the surface, those used in Upper Michigan being made of wood, have a wood surface which works very well. One table has a canvas surface, which is said to work well for certain grades of copper. I think that the best surface for the peculiar stuff to be treated can only be determined by experiment. I understand that in Germany much experimenting has been done in this line without fixing upon any one surface suitable to all materials and conditions; marble, slate, cement, wood, rubber, canvas, etc., each having been found best under as many variable conditions. This holds true with respect to nearly all machines, and many a machine that is doing its best in one place is condemned in another because it will not give as good results, under varying conditions, when perhaps only a slight modification in the machine itself was needed. As well condemn the saw that will not split the board it has so easily cut in two.

As to sizing the material for the table, I am not yet convinced as to the necessity for it, in copper dressing. It seems to me that the necessity for it is brought about only by poor separation at the jigs. With the separators usually used, the trouble has been that if enough hydraulic is used to keep the jigs free from slime, it carries over the tail of the separator a great deal of sand that should remain on the jigs, and which otherwise is detrimental to good work on the table. This is true of all separators where the excess of the hydraulic has to pass up through a narrow aperture, through which also the mineral must fall. I suppose as much effort has been made to secure a perfect separation as in any other line in mineral washing. Many have worked with a wrong end in view, and I may add in hydraulic separation, an impossible end, namely, a perfect sizing of the particles. Not only that, but for jigging purposes, a perfect sizing is not desirable, especially with the coarser sands; but as this is not within the province of slime treatment, I will not stop to discuss it.

However necessary it may be to classify the slimes, before going to the tables, it is certainly necessary to first get all the slime free from the sand that should remain on the jigs. I am glad to announce that this has at last been accomplished with the separator recently adopted by the Calumet & Hecla Company, and secured by letters patent. In the usual method of washing and separation, where the mineral has to drop through a narrow aperture, against a rapid and direct current of water, if the current is strong enough to keep back the heaviest particles of slime, it will also keep back the lighter particles of sand, suitable only for the jigs. Moreover, a great deal of the slime clings to the larger particles of the sand, and must be washed off in the separator if good work is desired. Heretofore I have seen no separator that would do this. In the new separator alluded to, the hydraulic is brought into each compartment from behind, by a pipe whose discharge is opposite to and near the spigot. Over this pipe and spigot is placed an adjustable shield which controls the hydraulic so that it reacts with a uniform current against the mineral seeking egress through the spigot, effectually washing all the slime from the particles suitable for the jig. This process being repeated at each spigot as far as carried for the jigs, carries away the slime, leaving the jig-tails perfectly clear, while the tables reveal the fact that no sand suitable for jigging has been carried over. This is a very important part of slime treatment. These results are accomplished with from fifteen to twenty per cent less water, which very much facilitates the subsequent treatment of the slime. This separator was more fully described in a paper read before the Institute at its last meeting in Boston, by Prof. Robert H. Richards, of the Institute of Technology in Boston. The slimes of the Calumet & Hecla assay from 1·2 to 1·3 per cent, the tails of the Evans table going away at about 0·65 per cent—results that are very good, considering that no free copper is found in the tailings. No matter how finely subdivided these sands may be, the particles still contain a finer particle of copper.

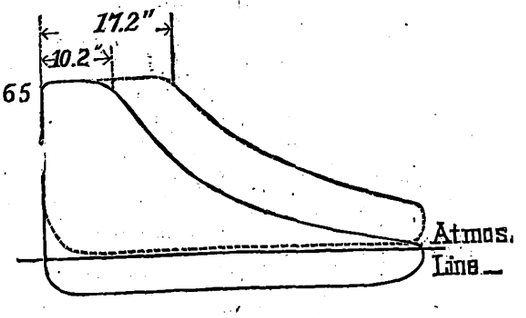
Thanks are due to the Calumet & Hecla Mining Company, which has been so liberal in its search for the best appliances, and which has seconded the efforts of those out of whose research and experience these results have come.

THE LAW AS AFFECTING MINING AND METALLURGICAL INTERESTS.



Unofficial Surveys.—The Wisconsin Mining Company, claimant of the Eureka lode No. 2, Colorado, protested to the Commissioner of the General Land-Office against the issuance of patent to John M. Cooper, for his claim upon the Chrysolite lode. The protest is in substance that "the published and posted notices failed to note as conflicting, as adjoining the prior claim of the Wisconsin Mining Company, which crosses the Chrysolite about five hundred feet from the eastern extremity. The plat and field-notes fail to show any conflict with the Eureka No. 2, although the latter had been previously surveyed, and neglected to indicate a thirty-foot tunnel, the property of the protestant, lying within the limits of the Chrysolite claim." By reason of these omissions, it is claimed that the protestant was unable, either by reading the published notices, or by an examination of the plat and field-notes, to ascertain or know, and did not ascertain or know, that said so-called Chrysolite in any manner conflicted with the Eureka No. 2.

The commissioner says: "The survey of, the Eureka No. 2, though prior to that of the Chrysolite, was not official; and there is nothing in the regulations of this office that would require a deputy to note conflicting surveys other than those made by or under the direction of the Surveyor-General. The existence of such a survey in this instance may have been well known, and it could therefore have been readily noted; but such is not always the case; and to require that every survey, whether of record or not, shall be noted, would in many cases work unnecessary hardships, particularly if a failure to recognize such survey was held to invalidate the notice given to adverse claimants. The Surveyor-General may make regulations for the guidance of his deputies in the performance of their work; but a failure to comply therewith does not necessarily annul a survey, unless the same fails to conform with the law. The published and posted notices were, in my opinion, sufficient to have put the protestant upon inquiry, particularly when all the circumstances in connection therewith are considered. The Chrysolite claim must have been well known, both by name and reputation, to protestant, better in fact than the unofficial survey of the Eureka No. 2 could have been to the Chrysolite claimant. It is admitted that the published and posted notices were read with a view of ascertaining if any conflict existed, but this fact could not be ascertained. It is difficult to understand how this could have happened, how any one could have been misled when the name of the claim, of the claimant, the mining district, and county are all given, together with the names of claims on the northeast and south, and the course and distance to a well-known and neighboring rocky bluff. When these facts are taken into consideration, and it is also known that all the workings upon both claims are within three hundred feet of each other, it must be conceded that the relative positions of the two claims were known to protestant when the application for the Chrysolite was made, and that the notice given was all that the law contemplates as could be required thereunder. The real question to be considered is, Would the Chrysolite notice of application for patent have been misleading, had the Eureka No. 2 claim been unsurveyed, with no improvements belonging thereto lying within the Chrysolite boundaries, and said notice failed to give the gratuitous information as to a conflict, thought necessary by protestant? In view of what has been above explained, I do not think that such information could be reasonably insisted upon, the notice being already sufficiently specific, and hereby dismiss the protest."



THE directors of the Pennsylvania Coal Company, numbering over fifty, with friends, arrived at Wilkes-Barre June 18th, on a special train from New York. The leading coal operators of the city tendered them a banquet and ball at the Wyoming Valley Hotel.

THE DEANE INDEPENDENT CONDENSING APPARATUS.

We present upon this page an engraving of the improved independent condensing apparatus for high-pressure engines, manufactured by the Deane Steam-Pump Company of Holyoke, Mass., and also a reproduction of two indicator-cards taken successively from the same engine with all conditions of load, steam pressure, and speed remaining constant; but the exhaust in one case being carried to the atmosphere, and in the other to the condenser. These diagrams, of which the originals, with many others of similar character, are on file at the company's office, show very clearly the great saving of steam effected by the application of the condenser. When the exhaust is carried to the condenser, the vacuum therein removes atmospheric pressure and other resistance from that side of the engine piston, thus practically adding to the force on the piston, and allowing less pressure, and consequently an earlier cut-off of steam on the opposite side, to develop a given power, a corresponding saving of steam being thereby effected. If an increase of power rather than a reduction of steam consumption is the end sought, the condenser is equally useful; for with the cut-off remaining constant, and the power due to direct steam unchanged, the pressure of the atmosphere will be added, and the actual power developed by the engine largely augmented.

The style and general arrangement of the Deane condenser is clearly shown in the engraving; but an explanation of construction and manner of application may be of interest. The air-pump and condenser are shown on the left-hand side of the cut, and the steam end which drives the air-pump at the right. Containing motive power within itself, this apparatus is entirely independent of the working parts of the engine, and, without adding in the least to the load, renders its assistance in the most practical manner conceivable by taking up the work on the piston where the engine has laid it down, and obtaining an additional percentage of energy from the steam. The condenser is of the jet type, of approved design, and carefully proportioned, to its work. The injection-opening at the top is connected with a supply of cold water, and the opening at the side with the exhaust-pipe of the engine. The injection water flowing into the top strikes a perforated copper plate and descends in a shower to meet the current of exhaust steam rushing in through the side opening; condensation takes place, and a vacuum is produced or maintained, and the water continues its downward course into the pump, and is finally forced out through the discharge-opening in the air-cylinder cap and carried away by a suitable pipe. As this discharge-water has a temperature of one hundred degrees and upward, a portion of it is often used, if the quality of the injection supply admits of it, for boiler feeding, with economical results. A thoroughly reliable safety attachment on the condenser, shown below and at the left of the exhaust-inlet, is so arranged that, if from any cause water begins to rise in the condenser, the injection supply will be stopped, the exhaust automatically turned to the atmosphere, and the vacuum destroyed, thus effectually preventing accidents to the engine that have been so common with other forms of condensers. The air-cylinder of this apparatus is connected with the steam-cylinder by a set of polished wrought-iron tie-rods. The air-piston and steam-piston are connected by a suitable rod of composition metal, and where the rod enters the air-cylinder it is surrounded by a water-sealed stuffing-box, to prevent any leakage of air into the pump. The admission of steam to the steam-cylinder of this apparatus is controlled by mechanism of great simplicity, yet carefully worked out in detail. The valves are plain flat slide-valves, readily understood by any engineer, acknowledged to be the most durable of any, and when worn most easily repaired or replaced. The exhaust from this steam-cylinder is carried to the condenser, as shown in the cut, so that steam economy is secured at every point. It will be noticed that there are a number of hand-holes provided at suitable places on the air-pump and condenser, to give access to all valves and spaces. All valve-seats and bolts in the air-pump are made from composition metal, the air-cylinder is lined with composition, the piston is arranged for the use of patent fibrous packing, and we are informed that all working parts of both air and steam ends of the machine are made to gauge, and may be duplicated at any time with little delay or expense.

In regard to the practical value of the condenser in connection with the high-pressure type of engine, we suppose little comment is needed. It is generally acknowledged that where a supply of water for injection is available, no man can afford to run his engine with exhaust to the atmosphere.

The condensing apparatus here presented is a reliable and efficient machine, which has proved its merits by a number of years of practical work in all parts of the country, and on almost every style of engine, with success in every instance. On account of its independent arrange-

Digitized by Google

ment, it may be located in any convenient place in the engine-room, or, if preferred, in an adjoining room, or in another building, and the exhaust-pipe connected with it; and with no more care than an ordinary feed-pump requires, it will effect such a saving of steam as to render it emphatically a paying investment.

The amount of saving varies with different conditions and circumstances, but has been found in actual practice to be from 20 to 40 per cent of the total quantity required for a given power, due allowance being made for the steam used by the apparatus itself, or a corresponding increase of power may be obtained. The diagram given above was taken from a 20 by 48 Harris-Corliss engine, and shows a net saving of 38 per cent.

This apparatus requires no expensive foundation; it requires no head for the injection supply, and water twenty feet below the engine-room floor, or even more, if the condenser can be set below the floor, is available for this purpose. It is a first-class machine in every respect, and fully guaranteed by the manufacturers in material, workmanship, and operation. Further particulars in regard to this apparatus may be obtained from the Deane Steam Pump Company, Holyoke, Mass.

CRANES: A STUDY OF TYPES AND DETAILS.*

By Henry R. Towne, Stamford, Conn.

In the study of any special class of machines, it is often conducive to a better understanding of the subject clearly to enumerate the several types or forms in which the machine is used, and also to consider each of its more important details separately, rather than in their combination with other elements of the mechanism. It is proposed in the following pages thus to treat the subject of cranes.

The only English text-books descriptive of cranes are Glynn's, which treats of English practice in crane building as it existed more than thirty years ago, and sundry catalogues published by English dealers in machinery as a means of advertising the products of the various builders of cranes for whom they act as selling agents. The practice represented in the former is now almost obsolete, by reason of the improvements which have been effected, and the latter consist of little but a series of pictures of various cranes, without descriptive text, and with no information as to the details of their construction.

The building of cranes has long been recognized in Europe as one of the most important subjects in the field of mechanical engineering, and cranes of many forms are there seen applied to an almost infinite variety of uses. In America, on the contrary, cranes are but little used or appreciated, in comparison, at least, with the extent of their application in European countries. It is the purpose of this paper to present to American readers a brief classification and description of the most important types of cranes, and a similarly brief study of the more important elements entering into their construction, the object of the latter inquiry being to determine, if possible, the best forms of elements to be adopted.

With a better knowledge of crane construction will surely come a better appreciation of their economy and value as labor-saving machines. In hundreds of mills and workshops, heavy material is now moved and handled by manual labor at an expense so much in excess of the cost of doing the same work far more rapidly and conveniently by cranes, that the saving effected by the latter would yield an annual profit of from twenty to fifty per cent upon their first cost, while in many cases this outlay would be entirely repaid by the economy of one year's use.

CLASSIFICATION OF CRANES.

A *hoist* is a machine for raising and lowering weights. A *crane* is a hoist with the added capacity for moving the load in a lateral or horizontal direction.

All cranes, therefore, are provided with hoisting mechanism, and, in addition, must be capable of moving the load in one or more horizontal directions. This second function is effected in some types of cranes by simply pushing the load, in others by the operation of a distinct mechanism.

Cranes are most clearly classified by reference to their modes of transferring their loads horizontally; and, thus considered, are found to divide themselves into the following groups, namely:

1. *Rotary.*—In which the load is revolved around a fixed center, such as a mast or column.

2. *Rectilinear.*—In which the load is moved in straight lines in one or more directions.

Both types of cranes are subdivided into two general classes as to their movements, namely:

(*A.*) *Fixed.*—When their supporting members are fixed in some permanent location.

(*B.*) *Movable.*—When the crane as a whole can be moved about.

And into four other general classes as to their source of motive power, namely:

(*a.*) *Hand.*—When the motions, either vertical or horizontal, are effected by manual power.

(*b.*) *Power.*—When the motions are effected by power derived from line shafting driven by a stationary engine or other fixed motor.

(*c.*) *Steam.*—When the motive power is derived from a steam-engine attached directly to the crane itself and moving with it.

(*d.*) *Hydraulic.*—When the motive power consists of hydraulic pressure obtained from a pump or accumulator, and carried to the crane by pipes.

A further distinction is covered by the term locomotive, which is applied to cranes (usually of the rotary type) which are capable of propelling themselves upon a roadway or track.

Rotary cranes comprise the following principal types:

1. *Swing Cranes.*—In which the central mast is pivoted to the floor and roof of the building, and the load is suspended from a block fixed at the outer end of an arm projecting horizontally from the mast, the only horizontal motion being one of rotation.

2. *Jib Cranes.*—In which the central mast is pivoted to the floor and roof of the building, and the load is suspended from a trolley traveling in and out upon an arm or jib projecting laterally from the mast.

3. *Column Cranes.*—Which consist of a jib crane constructed to revolve around or upon a fixed column forming the support of a building or floor.

4. *Pillar Cranes.*—In which the central column or pillar is entirely supported by a heavy foundation built at its base, and the load is suspended from a boom projecting from the pillar and revolving with it or around it.

5. *Derrick Cranes.*—Which consist of a jib crane for yard use, the upper end or pivot of the mast being held in position by guy-rods or stays, instead of by attachment to a roof or ceiling.

6. *Walking Cranes.*—Which consist of a pillar or jib crane mounted on wheels, and arranged to travel by power or by hand upon one or more rails.

7. *Locomotive Cranes.*—Which consist of a pillar crane mounted on wheels, and provided with a steam-engine and boiler, the power of which is available for operating the crane and for propelling it upon its tracks.

Rectilinear Cranes comprise the following principal types:

1. *Bridge Cranes.*—In which a fixed bridge spans an opening, and the load is suspended from a truck or trolley capable of moving across the bridge.

2. *Tram Cranes.*—In which a truck or short bridge, from which the load is suspended, is arranged to travel longitudinally upon a pair of overhead rails, but is without capacity for transverse motion.

3. *Traveling Cranes.*—In which a rectangular space is provided with overhead tracks upon two opposite sides, and is spanned by a bridge arranged to travel longitudinally upon these tracks, the load being suspended from a truck or trolley capable of moving transversely across the bridge, so that the load may be moved to or from any point within the entire rectangle.

4. *Gantries.*—In which an overhead bridge is supported at each end by a frame or trestle extending downward and having wheels in its base to permit of travel upon two longitudinal tracks laid upon the ground so that the entire structure can move endwise upon the latter, and the load, which is suspended from a truck or trolley on the bridge, can be moved transversely across the bridge.

5. *Rotary Bridge Cranes.*—Which combine a rotary with a rectilinear movement and consist of a bridge having one end pivoted to a central pier or post, while the other or outer end travels on a circular overhead track or is supported by a gantry frame traveling upon a circular track upon the ground, the load being suspended from a truck or trolley traveling transversely across the bridge.

The above nomenclature will be adhered to in the following descriptions of crane construction.

HOISTING GEAR.

The most important factor in the economy and convenience of a crane is the mechanism by which the load is lifted and lowered, as it must necessarily come into action every time the crane is used.

In all applications of power, from whatever source derived, it must be remembered that the gearing of a machine can only modify the power applied in one of two ways, namely:

(1.) By reducing its velocity, and proportionally decreasing its force or "pull."

(2.) By increasing the velocity, and proportionally decreasing the intensity of the power transmitted.

Under no circumstances, unless the motive force is increased, can power be gained except by a sacrifice of speed, or can speed be increased except by a sacrifice in power. If either or both must be increased without diminishing the other, it can only be accomplished by supplying more motive power.

The function of gearing, then, is to change the force or direction of the power applied. If it is well designed and constructed, this may be done with only a small loss from friction; while, if badly made, the gearing may absorb much power in wasteful friction of its moving parts.

In machinery for hoisting, the "purchase," or conversion of velocity into lifting power, is usually effected partly by a multiplication of the ropes or chains of the tackle through which the load is suspended, and partly by gearing within the machine, which latter thus becomes an important feature in crane work. The gearing ordinarily used for this purpose consists either of spur-wheels and pinions, or of worm-wheels and worms, or both combined, and the smoothness and economy of power of the machine depend largely upon the manner in which the gearing is made.

A second feature of prime importance in the hoisting gear of a crane is the mode of sustaining the load, and guarding against its "running down" when the application of the motive power is discontinued. This has heretofore been accomplished, in machines having spur-gearing, by a ratchet-wheel, the pawl of which has to be entirely disengaged to permit lowering to occur, or by a brake which, when on, prevents all motion of the machine, and which requires to be held or thrown off both in hoisting and lowering. In machines having worm-gearing, the end is attained by a construction of their worm-wheels such that the friction between the worm and the wheel is sufficient to prevent the backward rotation of the worm under the pressure of the teeth of the worm-wheel caused by the load, the resistance thus generated sufficing to prevent the running down of the load.

The worm-wheel system is usually safe against accidents, but is not economical of power if the worm-gears are proportioned, as above explained, to hold the load suspended without running backward when the application of power ceases, as is usually the case. The spur-wheel system, on the other hand, is a constant and inevitable source of great danger both to the load and to the operator. With the least carelessness in lowering, the load begins to descend with great velocity, and the mechanism is driven backward with corresponding speed and violence. If not checked, the load then practically falls as if unsupported. If too suddenly checked, violent strain is thrown upon the entire frame of the crane and on its gearing, which latter is thus liable to damage, and even to "stripping" or fracture, in which event the load falls. Where spur-geared cranes are operated by hand, this "running down" of the load involves a reversing or "flying back" of the cranks, which then frequently strike the men before they can escape beyond their reach. Accidents of this kind, resulting in injury to limbs, and even in loss of life, are constantly happening with common cranes, and are reported almost daily in the newspapers.

It is possible, however, so to proportion worm-gearing as to place it

* A paper read at the Cleveland Meeting of the American Society of Mechanical Engineers.

Digitized by Google

almost, if not wholly, upon a parity with spur-gearing in regard to economy of power transmitted, and, by the use of cut worm-wheels driven by turned worms or pinions (the teeth of the wheel being formed by means of a chasing hob or cutter), so to construct worm-gearing that it becomes the best and most convenient form of gearing for use in crane mechanism. It is found that gearing thus made will not automatically support the load, and that the latter, if left suspended, will drive the worm-gearing backward; but in this case the descent of the load is quite slow, and no perceptible acceleration takes place, so that the worm-gears thus act as a governor to control the load. By the application of a small brake to the worm-shaft, this tendency is counteracted, and by connecting this brake with the levers which control the motions of the mechanism, the brake is easily made automatic, and thus securely holds the load whenever the crane mechanism is at rest.

In all cranes, except those of small size, provision should be made for one or more changes of speed in hoisting and lowering, so that the speed may be varied according to the load and the nature of the work to be done. Cranes operated by power *may* be so constructed that the maximum load can be lifted at the quickest speed; but they are usually so proportioned that this can be done only at a slow speed. By this plan, much economy of gearing, space, and cost is effected, and the practical efficiency of the crane for all ordinary uses is not impaired. The most perfect construction is one that permits a change of speeds to be made whether the hoisting gear is in motion or at rest, and which sustains the load automatically while a change of speed is making.

The hoisting gear of a crane should therefore attain the following results:

(1.) Such changes in direction and velocity of the power applied as will give the desired motions to the load.

(2.) The accomplishment of this with a minimum loss of power through friction.

(3.) The safety both of the operator and the load under all conditions; to insure which, the load must be always self-sustained and incapable of "running down."

(4.) Capacity for changes of speed and for convenient transition from one of these to another at will, whether the gearing is in motion or at rest, and for the automatic support of the load during the act of changing speeds.

TRAVERSE GEAR.

In this, as in the hoisting gear, good design and construction are essential to economy of power, and frequently to safety against accidents.

In some types of rotary cranes, no traverse mechanism exists, except an arrangement of parts which provides for the rotation of the crane. In others, such as jib and derrick cranes, provision must also be made for moving the truck or trolley horizontally on the jib, and the same provision is required for moving the trolley of bridge and traveling cranes transversely on the bridge. In all such cases, a separate mechanism, distinct from the hoisting-gear, has heretofore been employed, and is still sometimes desirable or convenient. When employed, its parts should be as few and simple as possible, and it should be so far independent of the hoisting-gear as to permit either to be used at any time separately or conjointly. In power cranes, provision should be made for accelerating the speed of the trolley travel whenever the nature of the work admits of it. The best possible result is attained when travel of the trolley is effected without varying the vertical position of the load, and without causing useless movement of the hoisting chain or rope over the sheaves through which it supports the load, which movement would involve much additional friction, and cause rapid wear of the chain or rope.

In traveling cranes, a point of great importance is the parallelism of the bridge travel with the longitudinal tracks. Any defect here results in increased resistance to traction, and any considerable error might cause derailment. In traveling cranes, as heretofore built, the use of flanged wheels has been relied upon to prevent derailment, and the propulsion of the bridge has been effected by a transverse shaft extending the whole length of the bridge, and connected by gearing with the truck-wheels supporting each end of the bridge, so that, by revolving the shaft, the truck-wheels would be rotated, and the bridge be thereby propelled, provided the adhesion between the wheels and the rails was sufficient. In some instances, where the adhesion has not been sufficient to prevent slipping, a cast-iron rack has been laid adjacent to the longitudinal tracks, and extending their whole length, and pinions, gearing into this rack, attached to the axles of the truck-wheels, so that propulsion is effected independently of the adhesion of the truck-wheels to the track. If the load were always central on the bridge, and the motive power always applied to this shaft at the center of its length, this plan would answer well, although it is somewhat clumsy; but in practice the load is constantly varying in position, and the motive power is applied at one end of the long transverse shaft, so that torsion of the shaft induces a considerable variation in the travel of the opposite ends of the bridge. This error is a constantly varying one, according to the portion of the load resting upon each truck, as determined by the position of the trolley, the load being never equally distributed between the two trucks, except when it is exactly in the center. It follows, therefore, that this system of bridge travel, although operative, is radically defective, and that its use involves a constant loss of power by needless friction, and entails a proportionate amount of wear and tear of rails, wheels, and driving gear.

A better and more simple method of bridge propulsion has lately been introduced, by means of which the longitudinal motions of the bridge are effected by *pulling* each of its ends, simultaneously and at equal speed, in the desired direction. For this purpose, light wire cables are used, which, by a very simple and ingenious arrangement of guide-sheaves, are made to act as a "squaring device," to hold the bridge at all times perpendicular or square to the tracks upon which it travels. By this system, the friction of traction is reduced to a minimum, and the danger of derailment from unequal travel of the opposite ends of the bridge entirely obviated.

From the above facts, it becomes evident that a perfect system of bridge propulsion must hold the bridge always absolutely square with its tracks, and must propel the opposite ends of the bridge in the same direction, at the same time and at the same speed, however, unequally the load may be distributed. It is desirable also that, in large cranes at least, provision be made for starting the bridge slowly from a state of rest, and then increasing the speed, and also for varying the speed while the bridge is in motion.

CHAINS VERSUS ROPES, AND CHAIN-WHEELS VERSUS DRUMS.

In almost every type of crane, the load is primarily carried upon a flexible cord of some kind. This usually consists of rope, either hemp or wire, or of chain. Each of these has distinctive merits and objections.

Ropes have the advantage of being formed of many parts or fibers, so that no splicing or welding is necessary in their manufacture; and they thus have an assured and practically uniform strength throughout their length.

Chains, on the contrary, consist of a series of independent links, each of which is formed from a straight bar, and welded, so that a single imperfect weld injures the whole, the strength of a chain being obviously limited by the strength of its weakest link. By care and good workmanship, however, this danger can be avoided, in which case the chains becomes as safe as the rope, and much more durable.

Where a rope is used, the hoisting-gear must necessarily include a drum or barrel, upon which the rope is wound up when hoisting takes place. Chains may also be thus wound up on a barrel, and this has heretofore been the common practice when chains have been employed in crane construction, and a prominent feature in cranes of large capacity has usually been a proportionately large "winding-barrel" to receive the chain. A chain, however, admits of another mode of construction, which consists in substituting for the wide barrel or drum a pocketed "chain-wheel," consisting of a narrow wheel or sheave, of a width only slightly greater than that of the chain, and having formed upon its periphery a series of indentations or "pockets," exactly corresponding in size and shape with the links of the chain, so that the chain and the pockets fit together accurately, and slipping of the chain upon the chain-wheel becomes impossible. It thus follows that rotation of the chain-wheel causes positive motion of the chain at a speed equal to the circumferential velocity of the wheel, in a manner precisely similar to the motion of a rack driven by a pinion, or of one spur-wheel driven by another.

To be used in this way, it is necessary that the chain should have a constant and uniform "pitch," that is, that all the links should be exactly alike, so that the distance from link to link shall be always the same (just as in spur-gearing the spacing or pitch of the teeth must be uniform), and also that the pitch or spacing of the pockets of the chain-wheel corresponds accurately with the pitch of the chain. If this be done, and if the chain have a cross-section of such area that, when carrying the full load, it is not strained to its elastic limit, or to a degree which will cause any permanent elongation of its links, then a chain may be thus used, in engagement with a pocketed chain-wheel, as well and as safely as on a barrel. Indeed, a properly shaped wheel of this kind is much easier on the chain than a winding-barrel or drum, for the reason that the latter has a cylindrical surface, while the bearing face of the former is not cylindrical but polygonal, the bed or bottom of each pocket being tangential to the radius at its center, and so presenting a flat surface for the parallel sides of each alternate link to bear upon. When the chain is wrapped upon a cylindrical barrel, on the other hand, the straight sides of every alternate link, being tangential to the surface of the barrel, can each touch it at one point only, the link being unsupported throughout the rest of its length, and the tendency of the strain induced by the load is to bend each of these links to the contour of the barrel. This effect may be easily seen in any chain which has been wrapped, under severe strain, upon a cylindrical barrel, unless the diameter of the barrel be very large. The spiral grooving of a barrel does not remedy this fault, although it affords a much better bearing for the chain than a plain cylinder; which latter is only permissible for small chains and light loads.

For heavy cranes, hemp ropes are rarely used, owing to the size and multiplicity of parts required, and to their rapid wear. They are also inadmissible where liable to be exposed to much heat, as, for instance, in a foundry. Wire ropes are more available, and are often employed; but these also wear rapidly, unless the sheaves and barrels around which they pass are of large diameter, while this requirement, if met, reduces the effective hight of hoist and necessitates more parts or gearing to obtain the necessary purchase, and augments the bulkiness of the machine. Either material involves resort to a large winding-barrel or drum.

The usual and best device for large cranes is a well-made chain, and this, when used with pocketed chain-wheels and sheaves, gives the best and most satisfactory results, and leaves nothing to be desired. The adoption of this plan dispenses with winding-barrels, preserves the shape, and therefore the durability, of the links of the chain, and in every way simplifies and compacts the mechanism.

The relative merits of the several systems may now be summed up as follows:

(1.) *As to the Sustaining Cord.*

Hemp Ropes.—Admissible only for small cranes not in frequent use and not exposed to the weather or to heat.

Wire Ropes.—Available under any ordinary conditions, but involving a winding-barrel of large diameter and large sheaves; not economical of space.

Chains.—Possessing, if well made, all advantages and the greatest durability; *common chain*, requiring a winding-drum, but permitting it and the sheaves to be of smaller diameter than with wire rope; *pitch chain*, dispensing with a drum and admitting of the use of a narrow chain-wheel.

(2.) *As to the Winding Device for Hauling in and Paying Out the Rope or Chain.*

Winding-Drums or Barrels.—These must have a diameter and length such as will enable them to receive the whole length of rope or chain to be hauled in by winding it upon their surface in one coil, without overlapping. In large cranes, the load is usually carried upon four, six, or even eight parts of rope or chain, so that the length to be wound up amounts to four, six, or eight times the effective hoist, and the dimensions of the barrel thus become very large. Moreover, this barrel must either be caused to travel longitudinally on its shaft, so that the rope or chain as

Digitized by Google

it leads off shall be always in the center of the crane and hoisting mechanism (which method of construction involves serious complication and greatly widens the space occupied by the gearing), or the rope or chain, as it uncoils, be permitted to vary in position from one end to the other of the barrel, in which case it is nearly always out of center, thus inducing objectionable lateral strains and causing greater friction and wear.

Chain-Wheels, with Pockets.—These require a width only slightly greater than a single part of the chain, and a diameter merely sufficient to give the proper engagement with it, so that both dimensions become much smaller than in a winding-barrel, and the total space occupied is but a small fraction of that required for the latter device. The *chain-wheel* is fixed in direct line with the chain, and all lateral strains are avoided, while the flat bearings afforded for the chain by the pockets preserve the shape of the links and protect them from bending strains. The slack chain, after passing over the wheel, falls into a proper receptacle below.

From this analysis of the facts is deducted the proposition that chains, if well made, constitute the best form of flexible cord for sustaining the load in a crane, and that a well-constructed *chain-wheel* (as contradistinguished from a winding-barrel) is the best form of device for hauling in and paying out the chain; and therefore, the best method of crane construction involves the use of these two elements.

To visitors to the anthracite coal regions, it will be of interest to learn that the Mansion House, of Pottsville, situated in the heart of the mountains, on the line of the Philadelphia & Reading Railroad, has been entirely and newly refitted, and placed in thorough and complete order for the accommodation of summer and permanent guests. The management is in the hands of H. Hardell, late of the St. Cloud and Girard House, Philadelphia, who will leave nothing undone for the comfort and pleasure of his patrons. As a family hotel and a mountain summer resort, it is gaining in favor rapidly. A mountain park, twenty-five acres in extent, adjoins the house, which is exclusively reserved for the use of guests of the house.

FURNACE, MILL, AND FACTORY.

The Altoona rolling-mill has started on full-time.

Lock Ridge furnace, of the Thomas Iron Company, has blown out.

In the Railroad Exposition, the North Chicago Rolling-Mill Company exhibited a steel rail 130 feet in length, the longest rail ever rolled.

The Keystone Iron-Works, at Reading, which have been idle for some time, have resumed work.

The Greenwood rolling-mill, which has been closed since the failure of C. F. Schoener, has been leased by Daniel Shepp and H. A. Weldy, and will be started this week.

The puddlers at the Porkhouse mill, in Alleghany, have struck for an advance of one dollar a ton for boiling hard iron.

The Manchester Mills have recently sent in their third order for Curtis steam traps, the one this time calling for thirteen.

The charter of incorporation of the Beckwith Carbon Company was filed in the recorder's office on the 7th inst. The company will be located at Pittsburg, and will manufacture carbon points and plates for electrical purposes and crucibles. The stockholders and directors are James Renwick, John Turo, James Reinhart, John Neeley, Charles Corcoran, J. F. Armstrong, and Walter Beckwith. The capital stock is $20,000, and the stock is valued at $50 per share.

The Phœnix furnace of Brown, Bonnell & Co., Youngstown, O., is again in blast.

The Rosena furnace in New Castle, O., is engaged in filling an order for 6000 tons of Bessemer iron.

A steam-hammer with a striking force of twenty-eight tons, and over thirty feet high, has just been completed at the hammer-works of Morgan, Williams & Co., in Alliance.

The Birmingham, Ala., *Age* says: Two years ago, only two furnaces were in the city; now, five furnaces are ready for business. Two years ago, the sites now occupied by Sloss furnaces Nos. 1 and 2, and Mary Pratt furnace, were only pine thickets; now, not only the three furnaces are there, but a little village has sprung up around them.

A. Garrison & Co., of Pittsburg, have sent a train of 3-high plate rolls, 31 by 112 inches, to the Springfield Iron Mill. They are building rolls for the Maumee Rolling-Mill Company, Toledo, O.

The Scranton Steel Company now has its works in Scranton in nearly full operation. In the rail mill, three steel rails are rolled at once, and four will be rolled at once when the mill is in full operation. The works use as fuel culm or coal-dust from a mine close by, which is burned on a patent grate. This fuel costs only ten cents per ton at the mine.

At the annual meeting of the Colorado Coal and Iron Company, the following were elected directors for the ensuing year: William J. Palmer, C. F. Woerishoffer, W. H. Hays, August Ruttan, John Scott, Henry Amy, D. C. Hodge, R. H. Lamborn, and H. H. Danforth. The annual report shows: Gross earnings, $4,175,313; operating expenses, $3,765,736; and net earnings, $509,577. The interest charges were $163,403, and premiums, discounts, bankers' commissions, and sundry old accounts charged to profit and loss, $138,112—a total of $301,515, leaving a net surplus of $208,062.

Powellton Furnace, near Saxton, Bedford County, is producing about seventy-five tons per day of the highest grade of iron, for which Mr. Powell finds a ready market, more iron being shipped in the month of May than any month since the furnace started. Mr. Powell intends to build a second furnace soon. He has ordered a new engine weighing 225 tons. He also intends to put up fifty more coke-ovens, making 155 in all.

The Bay View mills of the North Chicago Rolling-Mill Company have started, the scale having been signed. The furnaces will be lighted in the merchant mill, top and bottom, and in the fish-plate mill and puddle mills.

The Cambria Iron Company, of Johnstown, Pa., has received the contract for steel bombshells for the United States government, the metal to have a tensile strength of 90,000 pounds.

The bids for the new steel cruisers will be opened at the Navy Department July 2d. Secretary Chandler has given notice that the maximum amounts which the Navy Department will pay for the construction of these vessels are as follows: For 4300-ton ship, the Chicago, $1,248,000; for 3000-ton ships, Boston and Atlanta, $783,000 each; for dispatch-boat, not yet named, $399,000; and no bids in excess of these figures will be considered.

In passing by the works of the Cambria Iron Company, at Johnstown, Pa., recently, it was noticed that they were carrying a very heavy stock of ingots and blooms.

The well-known pump firm, Henry R. Worthington, has opened a branch at No. 95 Lake street, Chicago.

The Mahoning Furnace Company, of Armstrong County, Pa., made an assignment June 21st. The liabilities are $70,000, and the assets, it is claimed, $75,000.

At a meeting of the Western Nail Association on the 21st inst., to consider the advisability of curtailing the production by a suspension of operations, the matter was postponed till the next regular meeting, in consequence of some of the manufacturers desiring to replenish their stock.

It is understood that the directors of the Puget Sound Iron Company have in contemplation the building of a large rolling-mill at Irondale, Washington Territory.

The first meeting of stockholders of the Portsmouth Machine Company was held at Portsmouth, Monday, the 4th inst. It was voted that the capital stock comprise 1000 shares at $100 each, all of which has been subscribed. Frank Jones, C. H. Mendum, B. F. Webster, E. H. Winchester, William Ward, J. Albert Walker, M. Eldridge, N. W. Halley, and Edward S. Fay were elected directors. The company organized with Frank Jones, president; W. H. Hackett, clerk; Charles H. Mendum, treasurer, and proposes to erect a machine-shop.

The Pennsylvania Lead Company has contracted for the sinking of a well 4000 feet deep, with the hope of striking a vein of gas, with which to furnish heat for its smelting-works.

The Blakeney Foundry Company, of Springfield, Ohio, recently organized, is building extensive works at that place, for the manufacture of the Blakeney cupola-furnaces and general castings.

The Lewis Foundry and Machine Company (Limited), Pittsburg, Pa., is erecting an additional twelve-ton air-furnace in its malleable iron foundry.

The Richmond (Ind.) Foundry Company has been incorporated under State laws. The capital stock is $25,000, and the directors are Charles F. Coffin, Joseph Marchant, Charles H. Coffin, Turner W. Hayes, William F. Spencer, and William C. Shoemaker.

The Low Moor Iron Company, of Low Moor, Va., recently made a contract for a new double hoisting-engine, with double drum and cages complete, with W. H. Barber & Co., of Allentown, Pa. The engine was shipped about June 1st.

The Fall River (Mass.) Iron-Works will put in a new double Corliss engine of 350 horse-power, one side of which will run the puddling department and the other the plate mill. The old engines will be taken out and a new foundation laid. During the changes, a general overhauling of the machinery in the puddling department will be made. The alterations will require some six or eight weeks.

GENERAL MINING NEWS.

ALABAMA.

The Atlanta *Constitution* chronicles the fact that Colonel Peters, of Birmingham, Ala., has just sold 30,000 acres of mineral lands in Fayette and Walker counties to the Kentucky & Alabama Coal, Iron, and Land Company, for $99,600. The same gentleman had previously sold to the Tennessee & Alabama Coal and Iron Company 50,000 acres for $300,000. This was from the same two counties, and the purchasing company is composed of Nashville and Memphis investors. Their purchase embraces some of the best coal lands in the great Warrior field.

ARIZONA.

HOWELL SMELTING AND MINING COMPANY.—The company is said to be making remarkable progress. The Belle mine, which the company took under lease for three years, abounds in mineral almost from the surface, and in all of the extensive openings scarcely a foot of non-paying rock has been encountered. The company has upon the dump some 2600 tons of ore. To June 1st, the product was 1896 bars of gold and silver bullion, valued at $50,000, and the net profits are at the rate of $10,000 per month. It has been voted to increase the capital from 150,000 to 250,000 shares by an issue of 62,500 shares of preferred and 37,500 of common stock. The company also has the Blue Dick mine, but has no occasion to work it while so much ore is piled upon the dump of the Belle.

GRAHAM COUNTY.

The Clifton *Clarion* reports as follows:

DETROIT COPPER COMPANY.—The Copper Mountain, Arizona Central, Montezuma, and Yankie mines are the property of this company. It is the intention of the management to run two furnaces as soon as tramways can be erected to raise copper from ore-bodies now uncovered. A main working-shaft is to be sunk immediately on Copper Mountain, on which will be placed a hoisting-engine. An improved California whim is also getting into position on the Yankie mine. The mines of this company are very happily adjusted. The gangue of the ore-veins in Copper Mountain carries enough iron to flux the carbonate ores Arizona Central and Lower Yankie.

GREAT WESTERN COPPER COMPANY.—These mines are located on Rocky Creek, about two miles north of the town of Oro, on the Frisco River. Prospecting on this property has been done mainly on the claim called the Olie, which is an extension of the Copper King lode. The vein-matter is a decomposed quartz, well filled with iron pyrites, with granite walls. The work done at present consists of a shaft sunk on the foot-wall of the vein about 72 feet, encountering good ore at a depth of 33 feet. At 50 feet, a cross-cut was made to the hanging-wall, cutting a two-foot streak of rich copper glance ore and exposing a fissure-vein which, at a depth of 50 feet, is 13½ feet wide. It is the intention of this company to continue the shaft to the depth of 100 feet.

CHASE CREEK.—A strike of sand carbonates has been made on the Lulu, one of the mines of this group. A shaft is sinking which is down 14 feet on the vein. Heretofore the Lulu, which is a well-developed mine, has produced copper ore exclusively from its working tunnel, which is in 240 feet.

CALIFORNIA.

MONO COUNTY—BODIE DISTRICT.

BODIE CONSOLIDATED.—During the past week, 166 tons of ore were crushed; average assay value, $33.50 per ton. Work east and west on the 1000 level shows no change.

STANDARD CONSOLIDATED.—Last week, the company extracted 1311 tons of ore, and shipped to the company $33,787 bullion. East cross-cut, 1200 level, is 301 feet long, and is in hard ground. North drift, 1000 level, is 177 feet long. South drift, same level, is in 118 feet. The vein is from 1 to 2½ feet wide, and continues to look well. The uprise from the 700 level is up 131 feet, where the vein is 4 feet wide.

SYNDICATE.—The mill is running steadily on Syndicate ore.

PLUMAS COUNTY—GREENVILLE DISTRICT.

During the past three years, prospecting for copper has been done on the mountain east of North Arm. Last year, a ledge was found cropping out at an elevation of about 1500 feet above the stream; a shaft was sunk forty feet, to test the vein, and the result being satisfactory, a tunnel was started that would cut into it at an additional depth of one hundred feet. This tunnel has now reached the ledge, which is found to be of great width, probably forty feet; the ore is estimated to contain as high as forty per cent of copper. On the surface, the ledge crops out for a long distance.

OPHIR CONSOLIDATED.—This claim is east of the Indian Valley mine, and contains two ledges, named respectively the Ophir and Primrose; these run parallel to each other, and are about one hundred feet apart. North and south, the claim is bounded by patented ground. In sinking a distance of only ten feet in the Primrose, the ledge opened out to over three times the initial width. The prospects of the Ophir ledge are also very encouraging.

YUBA COUNTY.

MILTON HYDRAULIC MINING COMPANY.—The reservoir, containing 650,000,000 cubic feet of water, burst on the afternoon of June 18th. The rush of

Digitized by Google

water was irresistible, and swept away every thing in its path. It raised the Middle Yuba River 100 feet. The roar of the running water was heard at several miles' distance. Several lives are reported as lost. The loss on the reservoir amounts to $75,000.

CANADA.

PROVINCE OF ONTARIO.

DOMINION PHOSPHATE MINING COMPANY.—A large number of business men interested in phosphates met in Montreal recently, and organized a company for the purpose of phosphate mining.

COLORADO.

CHAFFEE COUNTY.

The marble discoveries on the northwest side of Monarch will be opened up for quarrying in a very short time. Such development as has already been done shows this new and valuable property to be of great extent, and the quality has been pronounced by experts to be very fine and beautiful. So far, the full extent has not been positively determined, but even at the present time such a large body has been uncovered as to warrant the employment of labor for the full development of it. Work upon it will be commenced in a short time.

OSHKOSH.—This property is but a short distance from Monarch, and of such easy approach that, at a small expense, its ore can be directly loaded upon the cars. Discovered in 1878, it remained in possesion of its locator till the following year, when development began, which has at intervals been continued up to the present time. After the discovery of the ore body was made, a tunnel of 135 feet was run, and ore taken out in sufficient quantities to prove beyond a doubt that the mineral existed in a large and well-defined body. Upon the resumption of work this spring, another tunnel was started, which, in a few feet, caught the vein, and is now, at a length of fifty feet, upon a body of ore, consisting of carbonates and galena. The mineral is upon the contact between blue and white lime, and as work proceeds is widening out and improving in value.

CLEAR CREEK COUNTY.

WORLAND MINING, MILLING, AND SMELTING COMPANY.—This company has expended large sums of money in opening up its mines and in building mills and smelters. The Freeland is worked through a tunnel that has now reached the great depth of 2700 feet. At the distance of 1200 feet from the mouth of the tunnel, a shaft was sunk on the vein to the depth of 480 feet. At a depth of 125 feet in this shaft, another level is run on the vein to the distance of 700 feet, and from this level stoping is done to the tunnel above. This mine has never heretofore been noted for the richness of its ores; but for the last 75 feet and in the breast of this level, ores of surpassing richness have come in. Franklinite, brittle silver, and carbonate of iron, the first and last heavy in gold, stand in great bodies from 3 to 5 feet in thickness. Of the amount of ore in sight, there could be mined daily 200 tons. The timbering in the mine is of the most substantial character. The timbering of the winze is in square sets. This company has a concentrator built at the tunnel entrance capable of handling 150 tons of ore per day of twenty-four hours, and in addition, in close proximity to the mine, is its smelter.

GILPIN COUNTY.

BOBTAIL.—A new process for the separation of the mineral from the tailings from stamp-mills has been placed in the stamp-mill of this company in Black Hawk.

EAST FLACK.—The lessees of this mine, south of the Hidden Treasure, will begin sinking in the main shaft, now 700 feet deep.

GUNNELL.—The production for the month of May was as follows: Retort gold, $4676.50; smelting ore sold, $8885.17; tailings sold, $209.83; total, $13,771.50.

ROLLINS.—Work has been resumed upon the placer claims of this company below Rollinsville.

WHITING AND BUTLER LODES.—Since the new lessees took hold of the Whiting, they have sunk the main shaft some distance, and are now sinking and drifting. The highest runs heretofore received from the stamp-mill dirt have been 3½ ounces gold per cord. In addition to the Whiting, which is a patented claim of 1300 feet, they have leased and bonded the Butler lode, a patented claim of 1100 feet. In the lower workings of the former, they have about eight inches of smelting ore, which is saved for the smelters. The outlook of both veins is encouraging, and improves as developments are continued.

LAKE COUNTY.

Late Leadville exchanges contain the following:

A. Y.—The first shaft on this property was started early in 1880. Since then, three shafts have been sunk to ore, hundreds of linear feet of levels driven, and thousands of cubic yards of ore and waste rock extracted. Inexpensive and modest as the plant on this property has been, it has handled incalculable amounts of water, and the mine up to the present time has produced 32,000 tons of ore, mostly of a fair grade. The latest developments consist of a new shaft, sunk several hundred feet north of any of the previous workings, and some distance higher up on the side of Iron Hill. The new shaft has lately attained a depth of 270 feet, striking ore and connecting with the workings of the mine from other shafts. The underground workings of the mine already extend nearly 100 feet north of the new shaft. A station has just been cut out at the foot of the shaft, and connection made on the west side. As soon as this work is completed, the sinking of the shaft to greater depth will be resumed, when levels can be driven intercepting the ore farther to the northward, in its dip below the present waterline.

CALIFORNIA GULCH.—The mines along California Gulch continue to make the largest production of any one section in the district. Beginning with the Robert Emmet mine and following the gulch to its head, a distance of nearly one and a half miles, almost every mine on the hills on each side is producing and shipping regularly. The largest production, of course, comes from the properties located on the Iron Silver belt where it crosses California Gulch, but very considerable amounts are also produced by the mining properties both east and west.

DUNKIN.—Thirty tons of ore, averaging thirty-two ounces per ton, were recently shipped. The mineral is sand, carrying some galena, and is surrounded by a low-grade iron. The ore was extracted from the northern portion of the mine, in which a great deal of exploration-work is in progress.

HENRIETT.—The north level from the incline running toward the mine has two to three feet of fine ore in a rise, and the prospects of a large body of ore in this portion of the mine are excellent.

MORNING STAR.—The sinking of the McHarg shaft has passed through the body of sand carbonates, and struck a mass of iron. The sand ore shows a thickness in the shaft of three feet. The water is coming into the shaft in such volume that the sinking has been suspended. It is now proposed to run a small drift for drainage and prospect purposes from the face of the lower Waterloo incline, connecting with the McHarg shaft. This drift will be about 125 feet in length, and it will require about thirty days to connect it with the shaft when the sinking of the McHarg is to be again resumed.

RUBY.—This mine has been sold to a St. Louis syndicate for $60,000.

SAMPSON & ESTY CONCENTRATOR.—This concentrating mill, situated in Big Evans Gulch, is now in fair running order. The perfection expected to be attained in concentrating ores, the result of practice and experience, has, however, not yet been reached, though better and more satisfactory work is done each succeeding day. At present, the capacity of the mill is limited to its crushing facilities; but as soon as the screens for additional sizing cylinders can be secured, the mill will be able to handle at least forty tons a day. So far, the works have been kept running on material from the Evening Star mine, which in its crude state returns but about four per cent in lead, and four ounces in silver to the ton. With such low-grade material, but very indifferent results can naturally be attained, and at best the product of the jigs and buddles is not very high.

SAN JUAN COUNTY.

It is stated that the North Star and Sultan have been sold for $475,000. Arrangements have been made by which the Martha Rose smelter will also pass into the control of the same company, which is said to be an English syndicate.

GUSTON.—This mine, situated on Red Mountain, has been sold to Eastern capitalists for $100,000. The purchasers propose to develop the mine extensively.

SUMMIT COUNTY.

The litigation between the Empire State and the Enterprise has assumed a new phase. Simultaneously with the nonsuit of the Empire State in the United States Court at Denver, that company instituted proceedings against the Germania Mining Company in the district court at Breckenridge. The question then arose whether the Germania Company should not be permitted to go on with its case in the land-office and perfect its patent, the owners of the Empire State having failed in their suit before Judge Hallett. Under the law, a party adversing an applicant is bound to bring suit within thirty days, and prosecute the same with due diligence. No decision has been rendered on the question, but it seems likely that the land-office will not forward the Enterprise papers to Washington, until the Empire State people have had an opportunity of establishing their claims before the district court.

CHAMPION TUNNEL.—In consequence of the withdrawal of steam from the Robinson, work had to be stopped at this mine. This property seems to get more deeply involved in trouble each week. At present, the interest of one of the lessees in the lease has been attached, and is to be sold under a judgment.

KEYSTONE BULLION COMPANY.—The works at Breckenridge have been started up. They were originally built and fitted up by the Summit County Smelting Company in 1880, but in consequence of litigation they were run only a few days. During last winter, a company was organized in Philadelphia with a capital of $100,000. The works were purchased, and have been thoroughly overhauled. The buildings are adjoining the town on the west bank of the Blue, occupying a commanding location. The machinery throughout is first-class, and together with the buildings cost the Summit County Smelting Company upward of $129,000. The principal source of supplies is the Union mine, on Mineral Hill, the Penn-Breckenridge mines, and the mines owned by Watson, Corning, and Boylan, on Nigger Hill, which furnish a sufficient variety for all smelting purposes. The owners of these extensive properties are also interested in the company. The location of the works is such that the grade is descending from all these properties, and also from the lime-rock ledges and source of fuel supply. There are now about 500 tons of low-grade ore at the works, and the capacity of the mines is sufficient to furnish a continual supply. The enterprise is now in good shape, so far as finances are concerned, the company having ample funds for the purchase of ore, and will, in addition to handling the product of the mines in which they are interested, conduct the business of sampling and purchasing ore in any quantity offered.

NEW YORK & SUMMIT COUNTY MINING COMPANY.—A correspondent of the Denver *Republican* writes that the company is getting through the large body of water that was encountered, and that it has now good prospects of soon reaching the main body of mineral that is before it, judging from the rich assays it gets from the small feeders in the wall. It is cutting through a large body of black quartz, carrying a large quantity of white iron, with copper pyrites, and has obtained assays from the feeders all the way from 30 to 350 ounces silver to the ton, and from $17 to $28 in gold per ton, 12 per cent copper and from 17 to 31 per cent lead. It is running a large force of men day and night. The company is determined to push the work.

ROBINSON.—The incline is flooded with water up to the 11th level. The mishap was partly due to the disabling of the great pump, but the surface water came in with such a flood after the incessant snows of April and May that no pump could have kept it under control. When the torrent subsides, it is expected that the mine can be pumped dry again in a day or two. Meanwhile, the ore-shipments for May were 92 cars, precisely the same amount as in April; and the shipments thus far in June are 16 cars, as against 11 cars for the same period last year. Nothing further has been done with the dry concentrator; about 100 tons of low-grade ore are shipping to the Greer concentrating-works at Kokomo. A dispatch from Leadville says that Mr. Greer, the lessee, has left there for New York. It is said that he will insist on a modification of the terms of the lease, and that, if he fails to obtain this, he will relinquish the lease. It is reported here that the mine has run behind.

WHITE QUAIL.—Work has not yet been resumed at this mine.

DAKOTA.

A dispatch from Deadwood says that intense excitement prevails throughout the Black Hills over recent discoveries of the greatest importance and value. The first was made about a week ago, but was kept quiet through uncertainty as to the character and value of the ore. Much development-work and many assays have since established the presence of tin in large bodies, running from 50 to 55 per cent tin and with traces of gold and silver. The mine is situated three miles from Harney's Peak, and is in a micaceous formation.

The second discovery was made in the St. Elmo, a gold mine six miles from Custer, near the Sidney stage-road. Work began on the mine two weeks ago, and was continued in good ore from the start. The ledge was cut to a width of 50 feet, and recently a streak of exceedingly rich ore was encountered. Pieces of rock pulverized, making less than a pan, yielded fully $40 gold. The ledge can be traced on the surface a long distance. Miners are flocking to the locality from every direction.

All the mills on the "belt," with the exception of the Gustin, are in operation.

A late dispatch says that little if any placer mining is under way in the Black Hills at present, owing largely to the destruction of flumes, ditches, boxes, etc., by the flood.

CALEDONIA.—The superintendent reports for the week ended June 10th: Ore produced, 1050 tons. Men on pay-roll, 112. The winze advanced 10 feet since work was resumed, making a total of 132 feet. About the last of this week, we shall have it down 100 feet vertical, when we shall begin drifting. The company is operating every stamp. Additional stamps will not be put in until the completion of the 200 level, which will, no doubt, demonstrate the propriety and necessity of increased milling facilities.

FATHER DE SMET.—The superintendent writes as follows, under date of June 4th: Herewith express company's receipt for bar No. 160, containing 848·15 ounces of gold, the result of run of mill for last half of May. This bar fully equals my expectations, as we were idle for three days on account of the flood, which filled open cuts, winzes, and tunnels with *débris*, which have all been cleaned up and run through the mill. We are doing much better now, and a good showing will be made for this month.

FLORENCE.—The enlarged silver mill will start up shortly.

NIGGER HILL.—It is reported that the forty-mile ditch scheme, begun a year ago, by this company, if not finally abandoned, is at least "laid over" for the season.

ILLINOIS.

MCWILLIAMS OIL COMPANY.—Oil has been struck in the company's new well, on the Simmon property, at Litchfield, at a depth of 675 feet. The oil is entirely free from water, and is pumped out at the rate of six barrels in twenty-four hours.

MEXICO.

The Consul of the United States, at Guaymas, Mexico, informs the Depart-

Digitized by Google

ment of State that of the miners from Arizona who, in the past three weeks, left that post for the Lower California gold placers, forty-five returned on June 10th. These men report that the placers contain little gold, and that their value has been grossly exaggerated ; that the nearest water is twelve miles from the mines, and even then only enough for drinking purposes ; that there is no pasturage for animals at or near the mines ; and that they advise no one to go there with the expectation of making money ; that the remainder of the miners are expected back in ten days, as they are waiting on the beach for a vessel ; and this may be considered as ending the excitement in connection with the gold placers in Lower California in latitude 28° 29′.

SANTA EDUWIGES.—Ex-Senator Tabor, of Denver, has purchased this mine, situated at Jesus Maria, State of Chihuahua.

MICHIGAN.

NONESUCH.—The stamp-mill is nearly ready to begin work.

SALISBURY.—At the mine, the working force has been slightly reduced of late, and now numbers but about thirty-five men. There are in stock some 20,000 tons of ore, but a quarter of which has been disposed of as yet. Operations this spring have been confined to getting out rock, timbering, and placing the mine in shape to produce ore quickly and advantageously when it is wanted—a condition which has been fulfilled. The force is now taking out from four to five hundred tons per week, and the product for this season can be run up to 50,000 tons if it is called for. The policy of the management is, however, not to push the output beyond the immediate demand.

TAMARACK.—The vertical shaft had reached a depth of 750 feet at the end of last week—having been sunk at the rate of over 60 feet per month (average(since the start. It has passed through seven belts of amygdaloid, two of which carry copper.

MONTANA.

BEAVER HEAD COUNTY.

HECLA CONSOLIDATED.—The Butte *Inter-Mountain* gives the following information :

The Cleopatra, the highest mine on Lion Mountain, has now reached the depth of 750 feet. In the past two years, it has produced 32,000 tons of ore. The vein or ore-chute runs from 4 to 30 feet in thickness, with an average width of 15 feet. The Ariadne and Mark Antony are on the same claim. The Ariadne shows a large vein on the surface, and will be worked extensively the coming summer. The Silver Quartz now shows a large body of the best ore ever found on the mountain. Atlantis and Fissure mines are beginning to look up. The Fissure mine has furnished over 30,000 tons of high-grade smelting ore, and can be made to furnish as much more. All the ore of the Atlantis is now dumped into and run out of the tunnel. The Lion Mountain tunnel is now connected with the Atlantis, and will be continued until connections have been made with the Sheep, Fissure, and Silver Quartz. Two hundred and thirty-five tons of first and second-class ores are now run daily over the Hecla and Greenwood tramway, a distance of three miles. Thirteen cars are run to the trip, and are let down by six brakemen with comparative ease and safety. The concentrator works 200 tons daily of crude ore. It is the intention to start both furnaces up on the first of the month, and to load the ore teams at the concentrator.

LEWIS & CLARKE COUNTY.

The construction train and first locomotive of the Northern Pacific Railroad arrived at Helena June 12th, amid the shouts and rejoicings of the people.

NEVADA.

SAFFORD DISTRICT.

ONONDAGA.—The present developments consist of an original tunnel on the north side of the center gouge, run in 75 feet, and a cross-cut north from near the end of the tunnel 30 feet north and 25 feet south, thus cutting the ledge 55 feet in width. The cross-cut passes through low-grade vein-matter, with spots of high-grade ore throughout the whole distance. The ore-body continues beyond both ends of the cross-cut to an undetermined extent on the south. Another tunnel has been started on the south side of the above-mentioned gouge, immediately below Tunnel No. 1, and is extended in 75 feet. This tunnel shows high-grade ore in the breast and on both sides as far as carried. Still another tunnel has been started to cut what is supposed to be the main foot-wall of the ledge, which is well defined, cropping out 400 feet in length and stripped to that extent, showing a vein of very rich ore varying from a few inches to three feet, with ore of a lower grade on the south side extending indefinitely. At the northern end of this development, a considerable amount of ore has been extracted and shipped, varying from 60 to 300 ounces per ton. The ore on the tunnel ledge near the northwestern boundary of the ledge has been exposed 300 feet, showing a large continuous vein, the whole distance in ore varying from 20 to 1060 ounces. At this point, which is 650 feet from the mouth of the tunnel and 500 feet vertically to the tunnel level, a shaft has been started with which the tunnel is to connect. The mine has shipped 69 tons of ore, which have been reduced at Salt Lake with a pulp-assay of 92 ounces for the first lot and 76 for the second. The mine can be worked by a series of tunnels on the ore-veins to a distance of 1000 feet, with an uprise of 600 feet, and can thus be delivered on the dump without the necessity of hoisting or the pumping of water.

ZANOLL.—The mine is situated about a half-mile below the Onondaga. In most respects, as regards the country-rock and the formation, it is identical with the Onondaga. The ledge, which is perfectly defined, extends northwest and southeast as in the Onondaga. The property has been prospected by a tunnel run from near the northwestern extension of the ground, running southerly into the mountain 250 feet. This tunnel, near its mouth, passed through a vein of low-grade ore which gave indications of a width of at least forty feet. A winze has been sunk thirty feet down from a point about 35 feet from the mouth of the tunnel, all in ore. Two hundred feet easterly from the line of the tunnel, a shaft has been sunk 112 feet on the ledge. At the surface, it was only a few inches wide, the ore of which assayed but $1.80 per ton, but has widened gradually to the bottom, where it is fully six feet wide. The character of the ore is carbonate of silver, with a gangue of iron and sulphate of baryta, carrying from 10 ounces to as high as 600 to the ton in silver, without gold. Traces of ruby silver are discernible in the ore, which bears a strong similarity at the bottom of the shaft to that found in the lowest development of the Onondaga. At the depth of 50 feet, a drift has been run on the ledge westerly to a distance of 40 feet, all in gray carbonate ore that assays from 40 ounces up to 612. Taken out without assorting, the entire vein-matter assays over 70 ounces per ton. One car-load of 26 tons has been shipped to Salt Lake for reduction, which pulped 72 ounces.

NEW MEXICO.

In the north end of the Sandia Mountains, about four or five miles from Bernalillo, miners while sinking a shaft discovered a six-foot vein of plumbago or graphite. The experiments made thus far show that it is equal if not superior to an article of foreign importation sold in American markets.

The new camp Fleming, the discovery of which dates back but forty days, is reported to be growing rapidly, having already some four hundred inhabitants. The camp was at first brought into prominence by the discovery of the Penrose and Old Man mines ; at the latter mine, thirty men are already employed, and the ore shipped to the Hubbs smelter shows rich returns. Various locations have been made, and high prices are demanded ; and the boom which generally accompanies the discovery of so-called bonanzas is at hand.

PENNSYLVANIA.

Reports by telegraph from Titusville state that the Grandin well, No. 9, which is situated outside of the oil development in Balltown, was unexpectedly completed June 15th, and began to produce largely. In the first hour, it produced twenty-five barrels, but in the second hour increased to fifty-five barrels. During the first twenty-four hours, it will yield between 400 and 500 barrels. This will possibly open a large amount of territory which hitherto has been considered useless, as traders have regarded the limits of the Balltown District as defined. This strike creates much excitement.

PATENTS GRANTED BY THE UNITED STATES PATENT-OFFICE.

GRANTED MAY 1ST, 1883.

276,576. Steam-Boiler or other Furnace. Charles Gearing, Pittsburg, Pa., Assignor of seven eighths to Samuel Harper, same place, and Henry P. Cooke, Lewis M. Hosea, and Charles F. Hesser, Cincinnati, O.
276,582. Stamp-Mill. Frank W. Hall, Dahlonega, Ga.
276,636. Furnace for Desulphurizing Ores. August Th. Schuessler, Newark, N. J.
276,691. Moving Grate for Boiler-Furnaces. De Witt C. Hill, Willimantic, Conn.
276,710. Dry-Ore Separator. Patrick W. Reardon, San José, Cal.
276,712. Machinery for and Method of Manufacturing Steel Railroad-Rails. Jacob Reese, Pittsburg, Pa.
276,738. Ore-Concentrator. William S. Ward, Leadville, Colo.
276,775. Ore-Concentrator. Alexander D. Clarke, New York City.
276,790. Hot-Blast for Blast-Furnaces. H. William Ellicott, Baltimore, Md.
276,861. Dry-Pressing Brick-Machine. Henry B. Morrison and George Willett, Motley, Minn.
276,903. Furnace for Steam-Boilers. Joseph G. Sextro, Carthage, O.

GRANTED MAY 8TH.

276,991. Brick-Machine. James C. Anderson, Highland Park, Ill.
276,997. Apparatus for Extracting Gold and Silver from their Ores. Richard Barker, London, County of Middlesex, England.
277,071. Crusher and Pulverizer. Morrill A. Shepard, Lebanon, Ill.
277,079. Reversing-Valve for Furnaces, and Device for Operating the Same. Henry Swindell, Alleghany City, Pa.
277,134. Crushing-Mill. Frank A. Huntington, San Francisco, Cal.
277,233. Ore-Crushing Machine. William Clark, Brooklyn, Md.
277,244. Rock-Drilling Machine. Henry Dunham, Glen Aubrey, N. Y.
277,277. Apparatus for Melting and Mixing Bituminous Compounds. Brierley D. Healey, Liverpool, County of Lancaster, England.
277,316. Amalgamator. Harrison B. Meech, Chatham, N. Y.
277,361. Steam-Boiler Furnace. Richard L. Slater, San Francisco, Cal., Assignor to Perkins H. Bagley, same place.
277,407. Furnace. Gustavus E. Buschick, Chicago, Ill., Assignor of one half to Charles E. Gregory, same place.
277,421. Brick-Kiln. Willis N. Graves, St. Louis, Mo., Assignor of one half to the Hydraulic Press Brick Company, same place.

GRANTED MAY 15TH.

277,491. Grate for Furnaces. Thomas Kirkwood, Chicago, Ill.
277,505. Process of and Apparatus for the Recovery of Turpentine and other Wood Products and for the Manufacture of Charcoal. H. M. Pierce, Chicago, Ill.
277,530. Machine for Separating Impurities from Coal. Charles W. Ziegler, Scranton, Pa.
277,538. Furnace-Grate. Christian H. Baush, Holyoke, Mass.
277,543. Rotary Crusher. David Bushman, Quincy, Cal.
277,578. Ore-Crusher and Pulverizer. James H. Kirkhead, Reno, Nev., Assignor of one half to Pierce Evans, same place.
277,638. Water-Bosh for Blast-Furnaces. Arthur F. Wendt, New York City.
277,661. Valve for Vapor-Burners. David E. Bangs, Medford, Mass.
277,666. Feed Mechanism for Ore-Crushers. Theodore A. Blake, New Haven, Conn.
277,746. Multiple Milling-Machine. William Krutzsch, Daytoa, Ohio, Assignor to the Buckeye Iron and Brass Works, same place.
277,762. Hydraulic Mining Apparatus. John H. Martin, Bidwell's Bar, Cal.
277,763. Ore-Crusher and Pulverizer. Robert McCully, Philadelphia, Pa.
277,815. Rolling-Mill. Samuel T. Wellman, Cleveland, Ohio.
277,817. Metal-Punching Machine. Moses G. Wilder and Charles T. Parry, Philadelphia, Pa., Assignors to said Parry, Edward H. Williams, William P. Henszey, Edward Longstreth, John H. Converse, and George Burnham, same place.
277,831. Apparatus for Making Bessemer Steel. Thomas H. Burridge, St. Louis, Mo., Assignor of one third to William L. Reynolds, same place.
277,850. Casting Attachment for Open-Hearth Steel-Melting Furnaces. Charles M. Ryder, Chester, Pa.
277,860. Rolling-Mill. Samuel T. Wellman, Cleveland, Ohio.

GRANTED MAY 22D.

277,884. Method of Reducing Metals from their Ores. John Clark, Silchester Road, Kensington, County of Middlesex, England.
277,885. Method of Reducing Metals from their Ores. John Clark, Silchester Road, Kensington, County of Middlesex, England.
277,889. Amalgamator. Henry Cook, Leadville, Colo.
277,929. Process of and Apparatus for Converting Cast-Iron into Cast-Steel. Jacob Reese, Pittsburg, Pa.
277,978. Smoke-Consuming Furnace. George Blackburn, Columbus, Ohio, Assignor to the Standard Boiler and Smoke-Consuming Furnace Company, same place.
277,989. Water-Jacket for Furnaces. John H. Canavan, Globe, Ariz.
278,013. Art of Manufacturing Iron, Steel, etc. James Henderson, Bellefonte, Pa.
278,019. Pumping Apparatus for Deep Wells and Mines. John H. Huffer, Jacksonville, Oreg., Assignor of one fourth to C. C. Beekman, same place.
278,035. Amalgamator and Settler. Frederick Morris, San Francisco, Cal.
278,059. Amalgamator. George W. Strong and Walter L. Strong, San Francisco, Cal
278,080. Brick-Kiln. Jacob H. Beidler, Mount Pulaski, Ill.
278,093. Apparatus for the Manufacture of Gas for Illuminating and Heating Purposes. Amos P. Chamberlain, London, England.
278,107. Apparatus for the Manufacture of Gas. Joseph E. Dowson, Westminster London, England.
278,145. Process of Generating Gas. Erazm. J. Jerzmanowski, New York City.
278,157. Coal-Hod. Emil G. Luscher, Bergen, N. Y.
278,160. Dry-Ore Separator. James Collins McCurdy, San Francisco, Cal.
278,168. Combined Gas-Engine and Air-Compressor. Lewis H. Nash, Brooklyn, Assignor to the National Meter Company, New York City.
278,209. Means for Burning Peat, etc., in Steam and Hot-Air Furnaces. William E. Wright, Rome, N. Y., Assignor to Anna Maria Wright, same place.
278,232. Pulverizing Machinery for Ores, etc. Willard M. Fuller, New York, Assignor of one half to F. S. Burr and J. B. Richmond, Brooklyn, N. Y.
278,234. Hot-Blast Stove. Frederick W. Gordon, Pittsburg, Pa., Assignor, by mesne assignments, to himself and James P. Witherow, same place.
278,250. Compound for Tempering Steel. John T. Mercer, Richmond, Ind., Assignor to himself, Edward F. Preston, Bismarck, Mich., and Samuel C. Richardson, Terre Haute, Ind.
278,279. Smelting-Furnace. Sherman G. Sackett, Denver, Colo.

REISSUE.

10,329. Gas-Furnace. George H. Baldwin, Hollidaysburg, Pa.

GRANTED MAY 29TH.

278,340. Machine for Rolling Tubes, Columns, etc. Charles Kellogg, Buffalo, N. Y.
278,343. Dumping-Car. Sidney D. King, Pittston, Pa.
278,363. Basic Bessemer Process. Jacob Reese, Pittsburg, Pa.
278,407. Machine for Grinding Minerals, etc. Thomas O. Cutler, Jersey City, N. J.
278,451. Valve-Gear for Steam-Engines. Eugene O'Neill, San Francisco, Cal.
278,496. Means for Utilizing the Waste Heat of Furnaces. William H. Brooks, New York City.
278,511. Ingot-Manipulator. Thomas Critchlow, Pittsburg, Pa.
278,512. Soaking-Furnace for Ingots. Thomas Critchlow, Pittsburg, Pa.
278,517. Rock-Drilling Apparatus. George McC. Derby, New York City.
278,593. Method of and Mold for Casting Steel Ingots having Iron Centers. John Pedder, Pittsburg, Pa.
278,629. Machine for Making Spikes and Bolts. William Taylor, Pittsburg, Pa., Assignor to the Angular Steel Nail Company (Limited), same place.
278,663. Molding Apparatus for the Manufacture of Pipe. William Ireton and Samuel E. Whitelock, Camden, N. J.

Digitized by Google

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, June 22.

Although the volume of business in the mining market has not been as large as last week, the character of the dealings has been better and prices stronger. Sonora continues to do a very large business, and also continues to decline. Robinson has been very actively dealt in, and has been weak under rumors that the lessee of the mine has demanded better terms for his contract, and that, if they are refused, he will turn the property over to the company. The Leadville stocks show some strength, especially Little Chief and Little Pittsburg. The Comstocks have been weak under small transactions. Eastern Oregon has been very actively dealt in at stronger prices. The total number of mining shares sold at all the Exchanges aggregates 169,048 shares, as against 176,418 last week.

The Comstock shares were very moderately dealt in, and were weak. California was quiet and weak, selling from 35@27c. Consolidated Virginia sold to the extent of 1000 shares at 63@58c. Mexican was quiet and steady, selling at $3.75. Consolidated Imperial sold at 8c. Gould & Curry records transactions of 100 shares at $2.65. Yellow Jacket sold at $4, and Best & Belcher at $4.25. Sutro Tunnel was quite active, and was a little weak; it sold from 24@21c., the business amounting to 24,800 shares.

The Leadville stocks record a moderate business at strong prices. Amie was quiet and steady, selling from 16@18c. Chrysolite had a small business and was steady, selling at $1.20. Dunkin sold at 20c., and Hibernia at 5c. Iron Silver was moderately dealt in at steady prices, selling from $2.90@3. Little Chief was very active in the early part of the week, and has been quite strong; it sold from 55@65@63c., the transactions aggregating 10,600 shares. Little Pittsburg had a fair business at strong prices; it sold from 90c.@$1.10. Climax was quiet and strong, selling from 5@9c.

The Bodie stocks were quiet and steady. Bodie Consolidated sold at $1. Standard had a small business at steady prices, selling at $6.50@$6.75. Bulwer was quiet and strong, selling from 80@85c.

The Tuscarora stocks have been quiet and strong. Belle Isle was quiet and very strong, selling from 40@71c. Navajo, with moderate transactions, was strong; it sold from $2.10@$2.25. North Belle Isle sold at 20c., with a business of 400 shares. Independence was quiet and steady, selling at 60c. Elko Consolidated was dealt in to-day for the first time this week; it was quite active and strong, selling to the extent of 15,400 shares at 20@30c.

In the miscellaneous list, Alice has been weak under a small business, selling from $2.75@$2.50. Caribou was quiet and steady at 13c. Eureka had a small business at steady prices, selling at $3@$4, the latter assessment paid. Green Mountain records moderate transactions, and was steady; it sold from 75@72c. Homestake was quiet and steady at $15.50. Horn-Silver was quiet and a little weak, selling from $6.75@$6.50. Robinson Consolidated has displayed considerable activity at declining prices; it sold from 75@51@53c., with a business of 28,350 shares. Sierra Grande has had a fair business at irregular prices; it sold from $1.25@$1.05@$1.20. Stormont was very quiet at 40c.

Alta-Montana was quiet and steady, selling at 3c. Caledonia sold to the extent of 100 shares at $1. Central Arizona had a small business at steady prices, selling at 30c. Decatur was very active, and was steady, selling from 4@5c. Durango sold from 6@7c. under a small business. Eastern Oregon has been very actively dealt in at stronger prices; it sold from 36@48c., the transactions aggregating 13,000 shares. Harlem was quiet and steady, selling at $1.40. Lacrosse sold from 11@12c. Oriental & Miller had a small business, and was a little weak; it sold from 19@15c. Rappahannock sold from 10@8c., with a small business. Sonora Consolidated has had a very large business at weakening prices; it declined from 26@21@22c., the business amounting to 24,800 shares. South Hite, with a business of 100 shares, sold at 10c.

MEETINGS.

Caribou Consolidated Mining Company, No. 18 Wall street, New York City. Annual meeting of stockholders and election of trustees, June 28th, at twelve o'clock M.

Salerno Mining and Milling Company, at the office of the President, William H. White, No. 353 Fifth avenue, New York City. Annual meeting of stockholders, July 2d, at four o'clock P.M.

DIVIDENDS.

The Bassick Mining Company, of Colorado, has declared its regular quarterly dividend of $100,000, or $1 per share, payable June 26th.

The Bulwer Consolidated Mining Company, of California, has declared a quarterly dividend of fifteen cents per share, payable July 2d, at the office of the Farmers' Loan and Trust Company.

The Contention Consolidated Mining Company, of Arizona, has declared a dividend of twenty-five cents per share, payable June 28th.

The Osceola Consolidated Mining Company, of Michigan, has declared a dividend (No. 15) of fifty cents per share, payable at the office of the company, No. 69 Devonshire or No. 246 Washington street, Boston, July 2d.

The Hope Mining Company, of Montana, has declared a dividend of $1.50 per share, payable July 2d, at the office of the company, 417 Olive street, St. Louis, Mo.

PIPE LINE CERTIFICATES.

The petroleum market has been very active this week, and at times considerable excitement prevailed. Free selling checked the upward movement, and notwithstanding a published report that a syndicate had been formed to advance the price to $1.50, the market has been depressed. Yesterday, the market was quite strong, but to-day the prices went lower and the market closed weak.

News from the oil regions during the week states that on Saturday last Grandin Well No. 9 came in a large producer, giving 494 barrels the first sixteen hours. On Monday, the Union Oil Company's well No. 5 came in good for 400 barrels the first twenty-four hours, and well No. 6 for 150 barrels. The Murphy well on lot 441 was reported dry. Yesterday, a large well, Balltown No. 3, came in good for 500 to 600 barrels the first twenty-four hours. To-day's news is, that Union No. 7, farthest north of Herrick land, was finished yesterday, and proved a failure. It is reported that the Anchor Oil Company bought a million barrels of oil yesterday at the average $1.16 per barrel and that the syndicate retired 900 certificates from Oil City banks. Balltown No. 3 gave 800 barrels first twenty-four hours, although it is stated that it will probably weaken very rapidly.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

		Opening.	Highest.	Lowest.	Closing.	Sales.
June	16....	$1.18⅞	$1.19	$1.17⅝	$1.19	1,182,000
	18....	1.19½	1.19⅝	1.16⅝	1.16½	2,109,000
	19....	1.16¾	1.18	1.13¼	1.14⅛	2,583,000

Total sales.....						16,400,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, June 21.

The market for copper stocks this week has not come up to the expectations which were indulged in in our last report, which may be accounted for in part by the dullness prevailing in the general stock market, and the want of confidence in the future. Ingot copper is steady at about 15@15¼c. for Lake, but the demand is light; and although at these prices the producing mines can make a good show for dividends, provided they can market their copper, still there is no disposition on the part of the general public to invest very deeply in this class of security. The sales of Calumet & Hecla this week aggregate just 14 shares at $243@245, the last sale of one share being at $241, closing $240 bid, and $243 asked. The holders of this stock are evidently content with the returns made to them, and manifest very little desire to sell, while at the same time the demand for it is not sufficient to advance the price to any extent. Franklin declined from $10¼ to $10, the old figure; only 300 shares changed hands. The promised dividend has not yet been declared, and there are some reasons to believe that it will not be made this year. Pewabic sold at $4, same as last week. Quincy has ruled extremely dull the past week; less than 50 shares sold at $49¾@$49½. Osceola declined on a small sa[le] $19, but subsequently a lot of 100 shares was tak[en] at $19½. The stock was in better demand to-day at $20 bid, with none offering. The rest of the list stupidly dull and inactive. The sales for the week, all told, were only a little over 500 shares; while the morning session of the Board to-day, not a singl transaction in mining stocks was recorded.

In silver stocks, there is much more activity. Bowman has been the feature at the Mining Exchange, and the prediction of last week has been fully verified, the stock selling to-day at 42c. per share against 17@22c. last week. The movement is purely speculative, as we are told there is nothing new from the cutlook at the mine to warrant the advance. Catalpa did not hold the advance of last week, but declined to 60c. on sales of about 3000 shares. Sullivan has maintained a good degree of firmness, with sales of about 2000 shares at $2@$1¾, the latter price being bid. Bonanza, steady at $2½. Harshaw, 50c. Silver Islet sold at $4, an advance of $1 over last week.

3 P.M.—The afternoon market shows no improvement. A lot of 50 shares Quincy sold at $49; closing, $48 bid. Franklin was offered at $10¼. Catalpa, 60c. bid, 62½c. asked. Crescent offered at 25c. Sullivan sold at $1½ and bid, $1⅞ asked. Harshaw, 50c. bid.

BULLION MARKET.

NEW YORK, Friday Evening, June 22.

There has been an active inquiry for silver in London the past week, resulting in an advance there and here. But for the weakness of our sterling exchange market, the figures here would be higher.

DATE.	London Pence.	N. Y. Cents.	DATE.	London Pence.	N. Y. Cents.
June 16	50½@50¼	109⅞	June 20	50⅝@50½	110⅜
18	50¼	109⅞	21	50 9-16	110½
19	50¼	110	22	50⅝@50¾	110⅝

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended June 22d, as compiled from various sources, amounted to $131,000, as against $151,000 reported for the previous week. The receipts from January 1st, 1883, to date are $5,691,713.53.

Foreign Bank Statements.—The governors of the Bank of England, at their regular meeting, made no change in the bank's minimum rate for discount, and it remains at 4 per cent. During the week, the bank gained £697,000 bullion, and the proportion of its reserve to its liabilities was raised from 39¾ to 41 per cent, against 46 1-16 per cent a year ago. June 21st, the bank made a further gain of £150,000 bullion on balance. The weekl statement of the Bank of France shows a loss

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14⅛ per cent, to arrive at actual value.

MINES.	States.	Month of May.	Year from Jan. 1st, 1883.

METALS.

NEW YORK, Friday Evening, June 21.

Copper.—Business has been very quiet, as it naturally is after the large consumers are well supplied. Although nominally held at 15½c., Lake copper is offering as low as 15⅛c. in moderate-sized lots, and better bids than 15c. are not obtainable. Other brands are dull, 14½c. being asked for Arizona, but there is no buying, and outside brands do not range better than 14@14⅝c., with the market in buyers' favor so far as less well-known brands are concerned. It is not probable that the struggle for placing these brands will be so severe at such prices as it has been, because the figures which can be realized by shipment to England are relatively much better than they were.

The Board of Trade returns for the first five months of the year are as follows:

	Jan. 1 to May 31. 1883.	1882.	1881.
Imports:	Tons.	Tons.	Tons.
Pure in pyrites	7,402	6,938	5,803
" precipitate	9,106	7,158	8,800
" ore	5,680	4,851	4,560
" regulus	4,135	3,229	2,011
Bars, cakes, etc.	14,800	14,034	10,992
	41,123	36,210	32,166
Exports:			
Raw (English)	7,479	4,550	7,533
Sheets	6,617	6,238	5,754
Yellow metal at 60 per cent	4,764	4,585	3,702
Brass at 70 per cent	1,424	1,282	1,251
	20,284	16,655	18,240
Foreign	4,784	4,813	4,575
	25,068	21,468	22,815

Tin.—The week has been a dull one, with quotations at the close at 20¾@20⅞c. cash for spot Straits and Malacca; 21⅛@21⅛ for Australian; and 21⅝@21¾ for Lamb & Flag. England cables at the close £98 15s.

Lead.—There has been considerable activity during the past few days, sales of Common and Corroding aggregating 1000 tons, including present, July, and August delivery, a little in the beginning at 4·40c., but the bulk at 4·42½c. The lead has been quite widely distributed, and has been sold by a number of parties. In spite of the heavy and comparatively dull trade, the metal is well maintained.

Messrs. John Wahl & Co., of St. Louis, wire us as follows to-day:

There is no change of any description in our market. Sales aggregate 230 tons of Refined at 4·13c. There have been no sales of Hard lead, which is nominally 4·12½c.

Messrs. Everett & Post, of Chicago, send us the following dispatch:

Our market is quiet and firm; we note sales of 300 tons of Common and Refined at 4·15c. and 4·17c., and one hundred tons at 4·20c. It is noticeable that there is more demand.

Spelter.—This metal continues quiet and dull, with quotations at 4·40@4·50c. for ordinary to good Domestic, and 5⅛@5·15c. for Silesian.

Antimony.—Some small spot lots are pressing on the market, which we quote: Hallett's 9⅝c., and Cookson's 10⅝c.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, June 21.

American Pig.—The principal feature in the market is the comparative scarcity of No. 1 Foundry. Though the leading makers still carry stocks figuring by thousands of tons, the bulk of the metal they hold is No. 2 and Forge, so that there has been a stiffening tendency in the best known brands of No. 1, some of which are bringing as high as $22 at tide-water. Ordinary brands are still quoted low, in some instances, $19.50. In No. 2, the supply is more than ample, and we can not note any marked improvement; but the feeling seems to prevail that bottom has been reached. We quote $18.50@$19 for good to standard brands, while Gray Forge is unchanged at $17.50@$18.50. There is nothing to report in Bessemer pig, which is selling at $21.25@$21.50, while England quotes by cable 50s.@51s. 6d. Spiegeleisen is fairly active at $31@$31.50 for 20 per cent, and $25.50@$26 for 10 to 12 per cent.

Scotch Pig.—The better feeling in the higher grades of American Pig has given encouragement to importers of Scotch pig, though they can not as yet record any business worth mentioning. Arrivals are light, and the fact that under the new tariff there will be heavier freight engagements on goods generally, is giving a firmer tone to freights, which are now from 6s.@7s. 6d. At the Exchange, the following cable quotations were received yesterday: Coltness, 60s. 6d.; Langloan, 59s. 6d.; Summerlee, 57s.; Gartsherrie, 58s.; Glengarnock, at Ardrossan, 54s.; and Eglinton, at Ardrossan, 48s. 6d. Warrants to-day were 47s. 1d. We quote here, all ex ship, Coltness, $24@$24.50; Langloan, $24; Summerlee, $23.50@$24; Gartsherrie, $23.50@$24; Glengarnock, $22.50; and Eglinton, $21.

Rails.—All the near-by mills are supplied with orders until the early or late fall. Nominal quotations are $38 at mill. England cables £4 15s.

Old Rails.—There have been some small sales on the basis of $22@$22.50.

Scrap.—There has been a little business in off lots ex ship. We quote $23.50@$24. Crop-ends are $24.

Philadelphia. June 21.

The following is an official report of the meeting of iron-masters held at the office of the American Iron and Steel Association this afternoon, in accordance with a call issued by the Executive Committee of Eastern Iron Manufacturers, appointed at Coney Island on August 24th, 1882, consisting of Messrs. Oliver Williams, Chairman; William E. S. Baker, Secretary; and A. H. Peacock, J. Avery Richards, and Jesse L. Cooley. The object of the meeting was to form a new schedule of prices for extra sizes of bars, rods, bands, hoops, ovals, plates, and sheets, so as to cover the changes made necessary by the new tariff. The principal mills in the East were represented by the gentlemen in attendance. An organization was effected by the election of Oliver Williams as president and William E. S. Baker as secretary. It was resolved not to change the rates on oval, half-oval, half-round, round, and square iron and on flat iron down to 4⅛ inches to 6 by 2⅛ inches to 8. The prices of larger flats were left to the discretion of the mills. The rates on band and hoop iron were referred for adjustment to Messrs. Nevegold, Cooley, and Williams, who are to report at a subsequent meeting. It was resolved to revive the Eastern Iron-Masters' Association, for the purpose of discussing trade questions. The Executive Committee was continued, and was authorized to call another meeting whenever it should be deemed advisable to have one. It will probably be called during the summer, to meet at the seaside.

Pig-Iron.—No. 1 Foundry has met with an improving demand and better prices. Several sales of 50 to 100-ton lots have been closed within twenty-four hours, and there is a much more active inquiry, owing to the fact that supplies are not as heavy in makers' hands as was supposed, and consumers have been adhering too closely to the "hand-to-mouth" policy. Some of the standard makers have orders in hand for more than they care to take just at this juncture, though this fact does not mean that consumers will find any difficulty in obtaining sufficient iron to answer all requirements. In other words, prices will remain steadier, at least for this number, while No. 2 is still weak and correspondingly lower. Sales of No. 1 have been made at $22 in some cases, and several brands at $21. Very little is offered below this. No. 2 iron is selling all the way from $19@$20. There is a better feeling among foundry-men, but it will remain a difficult matter to dispose of unusually large lots during the heat of summer. The blowing-out of additional furnaces is still talked of, and a few more will most likely go, but the supply will be equal to all probable needs of the trade. In Gray Forge iron, prices range from as low as $17 at furnace, to $19 for some special brands, which appear to be pretty well sold up. The inquiry for Forge is good, but buyers have shown an unwillingness to pay $18 for what they want, and makers think prices have gone as low as they ought to go. Transactions for 1000-ton lots are in hand. Some of the offers referred to, at $17, have been taken. The supply is still large, and there is no appearance of any upward tendency, principally on account of the fact that mills will want about one third less iron during the summer, and by the opening of fall, the trade will have got on to its feet once more.

Foreign Irons.—But little definite information can be obtained from the consumers of foreign iron as to the probable demands for the future. Sellers have nothing to say. Bessemer pig might be bought at $21. Domestic supply is still large, and there is less dependence on foreign sources. Scotch iron is selling without attracting special notice.

Merchant Irons.—Another declining tendency has manifested itself. Yesterday, country mills sold fair iron at 2·10c., delivered, and were anxious for all the business to be had at that figure. Some few mills get 2·20c., but that figure is high, although the few mills selling at that price are not short of orders. Other mills are anxious for business at 2·15c. The country mills look for a revival of Western competition, and are quoting low to protect themselves against it. Several inquiries for 50 to 100-ton lots were floating around this week, and were, no doubt, provided for at 2·10c.@2·15c. Skelp iron is moderately active.

Nails.—Large deliveries of nails were made this week, and prices range from $3@$3.20, according to

size of orders. Mills are doing an excellent business, and building requirements are heavy. Some speculative inquiries have been heard of, but the chances are too much against purchase of nails at this time. Interior nails are selling at $3.10.

Structural Iron.—Orders footing up 7000 or 8000 tons have been placed this week, mostly for bridge iron, and the inquiries in hand to-day show that there are a good many requirements coming forward that will prevent any further cutting of rates for the present. Angles are quoted nominally at 2·40c. Other shapes are unchanged.

Plate and Tank Iron.—A good week's business was done in a retail way, and some inquiry for large lots under consideration, the only difficulty being the unwillingness of buyers to pay current prices. There is not much danger of a downward tendency, as the requirements, as a rule, are large, and mills are able to keep going.

Sheet-Iron is in better demand for the fall trade.

Steel Rails are in active demand for late summer delivery at $39 in small lots, and negotiations have closed for two or three round lots for fall delivery at about $38, with offers for winter delivery at less. The week's business has been up to the average, and if concessions were made, some heavy orders could be reported.

Old material is unchanged at $22.50 asked, and $21.50 offered. No. 1 Scrap, $24 offered, and occasional sales.

Cleveland. June 19.

A fair volume of business is doing in pig-iron, though there is not entire confidence on the part of consumers in present prices. However, with stocks steadily decreasing, we think that furnace-men are justified in believing that the bottom has been reached, and that any change in the situation must be an improvement. Much, of course, of the future of the trade depends on our crops. Although the wheat crop is undoubtedly going to be short, indications at present are for a good corn crop, which will help us out. There are no large or speculative lots buying that we learn of, purchasing seeming to be for actual short wants. We quote:

No. 1 Bessemer	$22.00@$23.00
" 1 Foundry, all ore	21.00@ 22.00
" 1 Foundry, cinder mixture	20.00@ 21.00
" 1 Soft Foundry	20.00@ 21.50
1 Open Silvery	19.50@ 20.00
Illirons	18.00@ 19.00
4 months f. o. b. cars furnaces.	
Nos. 1 and 2 Charcoal	$24.00@$26.00
" 3, 4, 5, and 6 Charcoal	25.00@ 26.50
Hanging Rock Charcoal	23.00@ 25.00
Strictly Cold-Blast Charcoal	25.50@ 30.00
4 months f. o. b. cars Cleveland.	
Bessemer ores	$7.00@ $8.00
Hematite ores	5.00@ 6.00

Pittsburg. June 20.

The iron trade in this city is in an exceedingly unsettled condition. Very few important transactions are coming to light. Buyers are waiting for unexpected happenings. In crude iron, the Marshall iron is still the source of uncertainty. Should it be precipitated upon the market, prices would suddenly decline. The uncertainty as to the course likely to be pursued with this large stock of iron prevents the trade from returning to its legitimate limits, and is used as an argument to break down prices from what they ought to be. The local furnaces continue to supply requirements, and hence keep out distant iron on account of commissions and freight incident to shipping. Anthracite Forge iron sells at $18; Lake ore Bessemer iron, $21.50; Coke iron, $17.50@$18; Charcoal iron, $26@$27. Offers have been made from 50 cents to in some cases $1 below these figures, but wants will not be provided for except for immediate requirements. Muck Bars are weak at $34@$34.50. Inquiry for merchant bar has fallen off because of the heavy production and the accumulation of stocks. Mills will shut down for from four to six weeks in some cases, and on the whole, there will be a heavy restriction of output. Prices are still at 2 cents, but there are fears of a break, which, if it starts, will be followed by all. Nails continue in quite active demand at $3 for car-load lots. Large shipments are made, and the demand is fully up to the supply. Gas and steam-pipe is selling at 70 and 10 off; boiler tubes, 55 and 5 off. Consumers are ordering with more freedom, and the trade outlook is good. Bessemer mills are well supplied with orders for from three to four months to come, but are able to take orders for summer delivery in a small way at $38.50. Fall and winter orders can be had at 50 cents to $1 less. Spikes are 2·60c.; Splice Bars, 2c.; Track Bolts, 3·25c. Old Rails are quoted at $22.50@$23 for immediate delivery, and offers are made at $22.25. But few transactions can be reported. The steel trade is in an unsatisfactory shape. Low-grade steels are cut, and mills are not working full time. Crop-ends are quoted nominally at $25. Selected Railroad Scrap, $24; Ordinary, $23.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, June 22.

Anthracite.

The anthracite coal trade continues dull. The announcement of an advance, semi-officially made, has fallen flat, and the happenings of the past week have fully confirmed the views as to the wisdom of the course adopted expressed in our last issue. The condition of the trade does not warrant any increase in the price, except in the best Lehigh coals, which are now and have for some time been selling for from 5 to 10 cents above the June circular prices. The position of the majority of the companies doing a large business in this city is not such that they can afford to check what buying there is by insisting upon higher prices. It is entirely out of the question, so far as those sizes used chiefly for manufacturing purposes are concerned, and we understand that, in view of this fact, the attempt to put up broken coal 10 cents, as first reported, has been abandoned. We can not help expressing the opinion that it would be wise to do the same for the other sizes.

Coal says editorially this week: The report that the Lehigh Valley Railroad has been leased by the Pennsylvania Railroad has been promptly denied by both the parties, and yet few in the coal trade doubt that some agreement, though perhaps not precisely in the nature of a lease, has been arrived at. The well-known antagonism between the management of the Pennsylvania and Lehigh railroad companies on the one hand, and the Philadelphia & Reading, New York Central, and Baltimore & Ohio companies on the other, gives color to the statement that a closer alliance between the two former companies has been effected, as an offset against the fusion between the Reading and Jersey Central companies. Both the Pennsylvania and Lehigh companies are financially very strong, and the latter has a very favorable traffic arrangement with the Erie, securing to it a well-nursed Western business. The Pennsylvania, with the support of the Lehigh Valley Company, is capable of wielding a tremendous power in the coal trade, and is in a position to inflict much injury when it sees fit to break prices in retaliation for real or imaginary wrongs. What the policy of the new allies will be, it is, of course, impossible to say. They have, of course, a very great interest in making the coal business a profitable one to themselves; but they may become possessed of the idea of hurting others seriously, even though they may injure themselves a little. The past history of railroad wars has shown, over and over again, that reason is little listened to in the heat of the battle.

Such are the comments we hear on every side in the coal trade. There is a feeling of uncertainty and uneasiness, which early events may set at rest. The strategic movements of the first half of the year may lead to a long period of peace, and the coal trade move along serenely, grappling with an increased output. There may be only a shuffle for position in the Western markets; but the manner in which the great powers are manoeuvering for position is not exactly calculated to make the trade feel comfortable.

Mr. John H. Jones, official accountant, has just published the following statement of the anthracite coal tonnage for May, 1883. The statement includes the entire production of anthracite coal, excepting that consumed by employés, and for steam and heating purposes about the mines:

	May, 1883.	For year 1883.	For year 1882.	Difference.
Phila. & Reading RR.	563,069	2,618,729	2,320,207	I. 298,522
Lehigh Valley RR.	*483,258	2,318,891	2,058,827	I. 259,974
Central RR. of N. J.	380,729	1,745,399	1,483,526	I. 261,872
Del., Lack. & W. RR.	391,239	1,802,036	1,591,201	I. 210,836
Del. & Hud. Canal Co	†266,264	1,243,814	1,094,770	I. 149,043
Penna. RR.	219,609	955,297	836,584	I. 118,713
Penna. Coal Co.	109,779	528,667	472,049	I. 56,618
N. Y., L. E. & W. RR	25,277	127,443	85,648	I. 41,795
Total	2,439,224	11,340,185	9,942,812	I. 1,397,373

* This amount includes the production of the mines of the State Line and Sullivan Railroad Company, amounting to 5789 tons.

† In addition, there were 37,949 tons transported from mines by the Delaware & Hudson Canal Company during May, which is included in tonnage of other interests.

The stock of coal on hand at tide-water shipping points, May 31st, 1883, was 645,377 tons; on April 30th, 1883, 719,232 tons; decrease, 73,855 tons.

Bituminous.

The trade during the week has been very dull. Current business is small and the competition for it very active, so that all sorts of prices are spoken of. We understand that coal shipped via Buffalo and the Erie Canal, by the Rochester & Pittsburg Railroad, was sold as low as $3.75, and that some Clearfield shippers are cutting under $4. We quote Clearfield $4@4.25, and Cumberland $4.15@$4.40, according to quality. The Chesapeake & Ohio Canal has reduced tolls to 90 cents to Georgetown and 95 cents to Alexandria.

STATISTICS OF COAL PRODUCTION.

Comparative statement of the production of anthracite coal for the week ended June 16th and year from January 1st:

TONS OF 2240 LBS.	1883. Week.	1883. Year.	1882. Week.	1882. Year.
Wyoming Region.				
D. & H. Canal Co..	99,026	1,603,119	81,556	1,372,920
D. L. & W. RR. Co.	107,637	2,017,009	112,507	1,799,620
Penna. Coal Co.	35,230	563,133	37,757	505,309
L. V. RR. Co.	25,193	465,543	37,843	470,109
P. & N. Y. RR. Co..	5,725	89,402	5,690	86,783
C. RR. of N. J.	58,602	1,091,737	59,656	982,286
Penna. Canal Co.	14,776	136,526	16,709	143,921
North & West Br. RR.		202,304		
	346,199	6,168,833	351,718	5,361,008
Lehigh Region.				
L. V. RR. Co.	129,117	2,100,789	120,834	1,936,052
C. RR. of N. J.	53,737	997,154	59,463	884,036
S. H. & W. B. RR.		20,235		18,000
	182,854	3,118,178	180,297	2,838,088
Schuylkill Region.				
P. & R. RR. Co.	196,250	2,956,319	148,095	2,588,237
Shamokin & Lykens Val.	31,806	589,669		463,444
	228,056	3,545,988	148,095	3,051,681
Sullivan Region.				
St Line&Sul.RR.Co.	1,239	27,440	1,229	23,384
Total	758,348	12,860,439	681,339	11,274,641
Increase		1,585,798		
Decrease				

The above table does not include the amount of coal consumed and sold at the mines, which is about six per cent of the whole production.

Total same time in 1878	6,699,864 tons.
" " " " 1879	10,982,190 "
" " " " 1880	9,507,469 "
" " " " 1881	11,446,667 "

The increase in shipments of Cumberland Coal over the Cumberland Branch and Cumberland & Pennsylvania railroads amounts to 299,573 tons, as compared with the corresponding period in 1882.

Belvidere-Delaware Railroad Report for the week ended June 16th:

	Week.	Year. 1883.	Year. 1882.
Coal for shipment at Coal Port (Trenton)	4,380	38,243	26,192
Coal for shipment at South Amboy	16,790	369,715	352,042
Coal for distribution	16,566	357,022	318,812
Coal for company's use	3,026	67,532	59,023
Total	40,762	822,512	756,069
Increase		66,441	
Decrease

THE New York Iron and Metal Exchange is enjoying a little boom of its own. The speculative interest in its future has been strong enough to carry the price of seats to over four hundred dollars.

WE learn that Dr. P. DE P. RICKETTS will start for the coast about the 7th of July, with a number of the members of the fourth year class in the School of Mines. The young men will visit most of the prominent smelting and milling establishments of Colorado, to familiarize themselves, under Dr. RICKETTS's instruction, with the practical metallurgy of gold and silver. Dr. RICKETTS will also visit one or two mines and milling properties, to report upon the same.

DURING the past year, a number of American desilverizing works have introduced with much success the use of steam for stirring the zinc into the bath of base bullion. In the beginning, a little trouble was experienced from the formation of explosive mixtures of hydrogen and air, but of late that drawback has been entirely overcome. The process is one that reduces the labor in desilverizing and saves time. Sometimes, steam is also introduced into the poor lead, when it contains a little too much silver to go to the softening furnaces. The steam then apparently acts chiefly in cooling the metal slowly and bringing to the surface the last traces of the rich silver, lead, and zinc alloy.

THE English technical journals have, with a suddenness that savors of an interested inspiration, discovered that the attempts to recover sulphur in the alkali manufacture have proved a failure both in England and in Germany. They hail this as a great piece of good news for the Rio Tinto, Tharsis, and other pyrites companies whose stocks, we presume, are to be boomed on the strength of it. While it would be a matter of considerable interest to American pyrites miners to see their Spanish rivals busy filling European orders, it is well for them not to be misled by the statements now given out. The great danger which threatens their prosperity is not the recovery of sulphur from the waste, but the abandonment of the Leblanc in favor of the Solvay process.

NEARLY one half of the year has passed, and we are now in a good position to compare the record of the first six months' railroad construction with that of the corresponding period in 1882. To say the least, it is not encouraging to the many industries which indirectly and directly look to the railroads as their best customers. The *Railroad Gazette* of this city, in this week's report of new mileage, places the total thus far reported this year at 1966 miles, against 4166 miles reported at the corresponding time last year. These figures, of course, are not claimed to represent fully the work done; but they do furnish an idea of the relative activity in railroad building, and warrant the statement roughly, that we are adding one half as much new mileage to our net-work of railroads this year as a year ago. The demand for materials for new construction is usually anticipated. The iron and steel put down into new tracks were ordered probably between six months and a year ago, so that the movements of promoters and capitalists in Wall Street and other financial centers, furnish a better indication of what is coming, and are more interesting to the iron trade than the figures indicating the business which, to a large extent, has already been attended to by mills and furnaces. In this light, the prospects are not encouraging, however fair, according to current mileage reports, the past may have been.

THE BUTTE-TOWN-SITE CONTEST.

The recent decision of Judge GALBRAITH, in Montana, declaring that there is no statute of the United States authorizing the department to insert in a patent for a lode claim any exceptions as to town-site rights, nor does the law make any such exceptions, and such exceptions are therefore void, is attracting wide-spread attention. The decision was rendered in the case where the owners of the Pawnbroker lode brought suit to determine the possessory right as to surface ground. There are several similar cases pending, involving a considerable area of the town-site of Butte. The case heard and decided was the Silver Bow Milling and Mining Company *vs.* W. A. CLARK *et al.* The suit was for ejectment; a jury was waived, and the case was tried by the court. The main facts were admitted in the pleadings, and the question of title therefore was one purely of law. The lode claim was located November, 1875, under the law of May 10th, 1872, and patent obtained January 15th, 1880. The patent contained the following provision, for the insertion of which the court says there is no law: "Excepting and excluding, however, from these presents all town property rights upon the surface, and these are hereby expressly excepted and excluded from the same, all houses, buildings, structures, lots, blocks, streets, alleys, or other municipal improvements on the surface of the above-described premises not belonging to the grantees herein, and all rights necessary or proper to the occupation, possession, and enjoyment of the same."

The town-site was patented in September, 1877, and contained a provision that no title should be thereby acquired "to any mine of gold, silver, cinnabar, or copper, or to any valid mining claim or possession held under existing laws of Congress." No adverse claim was filed against the issuing of either patent.

The points decided by the court are in brief as follows:

(1.) The Land Department has no right to insert in a patent any exception or reservation which the law does not authorize. If it is done, such exception or reservation is void and of no effect; and this may be shown at any time, either in an action at law or in a suit in equity.

(2.) A party receiving a patent from the United States is not bound by exceptions, reservations, or conditions inserted in the patent without authority of law.

(3.) There seems to be no law authorizing the Land Department to decide a conflict between a town-site and a lode claim.

(4.) By the location of the Pawnbroker claim in 1875, the locators, according to the Act of Congress of May 10th, 1872, acquired the "exclusive right of possession and the enjoyment of all the surface ground included within the lines of their location," etc. (Sec. 2322, U. S. Revised Statutes.) This act of Congress was of itself a grant of right of possession and the right to purchase. And the "exclusive right of pos-

Digitized by Google

session" granted is utterly inconsistent with a right in another to occupy or use the surface for town-site purposes.

(5.) No authority is given by the statutes to the officers of the Land Department to insert in a patent for a lode claim any exceptions as to town-site rights, and such exceptions are void.

(6.) The provision in the Butte town-site patent was authorized by Sec. 2392 U. S. Revised Statutes, and was properly inserted in the patent.

(7.) At the date of the town-site patent, the Pawnbroker was a valid mining claim, and no title to it passed by the town-site patent.

(8.) The patent for the Pawnbroker lode claim related to the location of the claim of 1875, and confirmed the right of possession.

(9.) The plaintiff's title, under the location in 1875 and the patent in 1880, was prior and superior in law to that of defendant's.

It is understood that this decision will stop proceedings in the minor courts in all of the other cases involving the right to a large area of the thriving town-site of Butte. Attorneys in Washington practicing before the Interior Department have always fought against inserting a town-site reservation in mineral patents, claiming that the Secretary in authorizing the same is exercising arbitrary power. Many mineral claimants have positively refused to receive their patents with this reservation, and they are still "on hand."

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. We do not hold ourselves responsible for the opinions of our correspondents.]

The Use of Gas Furnaces in Copper Smelting.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: As bearing upon the questions raised in a series of letters to the ENGINEERING AND MINING JOURNAL, I desire to submit the following facts on the use of gas furnaces in copper smelting:

The engineers of the Mansfeld Copper-Works saw the advantages which gas furnaces have over common coal furnaces, and adapted or tried to adapt them to their purposes. As early as 1867, they removed a Siemens furnace for heating sheet-copper at one of their rolling-mills, because it did not work satisfactorily. (See *Berggeist*, 1867. No. 61, p. 268.)

In 1871, they began roasting the concentrated matte in gas furnaces previous to extracting the silver according to Ziervogel's process. These furnaces have worked very satisfactorily. All details are kept a profound secret.

In 1868, they built a reverberatory furnace, according to Siemens's system, for concentrating matte. The furnace was worked for three years until 1871, and was then finally abandoned because it required one third more fuel than ordinary furnaces, and the repairs were frequent and expensive. They used removable tuyeres, and tried quite a number of devices; but they could not get it to work as cheaply as the others, and therefore abandoned it. No patent was taken out for this combination; but the results obtained were published; hence no patent can be obtained for this combination in the United States. These notices were published in the *Berggeist*, 1868, pp. 318, 361; 1869, p. 564; 1870, p. 428. *Berg-und Hüttenmännische Zeitung*, 1869, p. 389; 1871, p. 438; 1871, p. 306. *Kerl: Grundriss der Metallhüttenkunde*, 1881, p. 180.

In his article, Mr. Johnsson mentions the shaft-furnaces of the Mansfeld works; but was apparently not aware of the application of gas furnaces at those works for the very purposes which he advocates, namely, the removal of the iron and sulphur. No doubt gas furnaces were introduced at other copper-works, especially in England, long ago; but the matter has been kept secret, and hence we have no definite knowledge of them. Possibly Siemens or his representatives might be willing to furnish further information.

A. H. W.

FREIBERG, GERMANY, June 5.

Bessemerizing Copper Mattes.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: You have, during the past few months, published a number of articles and considerable correspondence on the working of copper mattes in the Bessemer converter. In replying to these articles, I will give you some details on this process, which works successfully in the establishments of the company which I formed to carry it out.

The idea of working copper mattes in a converter is not new; furthermore, it was only too natural that it should be brought out as soon as the use of this apparatus in the metallurgy of iron had become an established fact. Several attempts were made in Europe, and notably in England, by Mr. Hollway, but not one of them led to success. It could not be otherwise. In reality, these experimenters were content to make one or two trials in a steel converter, without giving any thought to the modifications which the very nature of the metal itself demanded. They were so sure of success that they did not take the trouble to seriously study the subject beforehand.

When I was called upon to go into this matter, I also met with failure in the same way. But I was convinced that it was impossible not to reach a completely favorable result, and I undertook methodically a series of experiments and studies, to which I owe the entire success which I have attained. In order to be more at liberty to work to suit myself, I built a small experimental plant with suitable blowing-engine, and a small converter, capable of treating one hundred kilograms of matte. My tests extended over two years, during which time I constantly modified either the arrangement of the plant or the process itself, until I at last arrived at a regular and perfect production.

These explanations may suffice to show why those who have attempted to solve this important question before me were unsuccessful. The converter, as used in steel-making, was not suitable for the work, and the owners of the works to whom application was made to authorize a trial could not allow them to be carried on for a long time, to modify the plant, etc. It was necessary, in order to reach a successful issue, to go to the expense of a special trial plant. That is what I did, and it is to this that I owe my success.

The following is a brief description of the work as carried out in our establishment, where there are only two operations.

1st. Melting the ore, without any previous roasting, in any suitable furnace, preferably a shaft-furnace, with the object of producing a copper matte.

2d. Casting the matte produced into a converter of special design (the "Manhès converter"), when, under the action of high-pressure blast, it is rapidly transformed into blister copper, carrying 98 or 99 per cent.

During the work in the converter, the temperature is kept very high by the combustion of the iron, sulphur, and other elements which oxidize more rapidly than copper. These substances must be present in given quantities, easily obtained by suitable additions. The oxides formed are rapidly converted into silicates by contact with the side-walls of the converter, and with additions especially provided for. A special design of the Manhès converter protects the copper from contact with the blast as soon as it is brought to the metallic state. Without this precaution, it would set solid, and the operation would be brought to an end without being completed. The operation is very simple, but I need hardly add that success depends upon many special arrangements and methods of handling, which are the result of two years' experience. As you will note, the process is characterized by the omission of all intermediate roasting and smelting processes, by the rapidity of the work and by its economy. According to local conditions, the saving in cost, compared with the Welsh or Swansea processes, is from 50 to 75 per cent, which is the result of the following:

1st. The reduction of the cost for labor to a minimum, because the operations last only a few minutes, and large quantities of metal can be produced rapidly and with little labor.

2d. The cost for fuel is very low, because no coal is necessary, except that for melting and an insignificant quantity for heating the apparatus before starting. I assume that water-power is available. If not, the fuel necessary to run the engines must be added.

I may add that, in consequence of the high temperature and the strong oxidizing action in the converter, arsenic, antimony, etc., are almost completely eliminated, so that the metal produced is always of good quality—a fact the importance of which will be evident to those familiar with the metallurgy of copper. The apparatus are simple, cheap, occupy little space, and are easily worked when their operation is once understood.

Our works are now completely organized, and consist of three melting-furnaces, each capable of putting through from 25 to 30 tons of ore per day; two small cupolas for remelting the matte in case of need; three Manhès converters, treating a ton and a half of matte in each operation; one converter, making from 22 to 24 operations per day; and the necessary blowing-engines. An establishment of such a capacity can be built rapidly and at a comparatively low cost, now that experimental work is over.

I come now to the different objections raised against my process in some articles published in your JOURNAL.

In a communication from one of your correspondents, he seeks to cast a doubt upon the economic advantages of my process, and raises points to which a true and logical reply has been made in your JOURNAL by Mr. H. M. Howe. I will only add that there are, in carrying out the process, a number of details of great importance, which I can not refer to at present, and which are the result of several years' experience.

Mr. Paul Johnsson wants to get at the same results by replacing the converter by a reverberatory furnace, in which he melts the matte. Then he oxidizes it by means of jets of air directed upon the surface of the bath through inclined tuyeres. This idea is not new, being almost as old as metallurgy itself. But the reverberatory can not replace the converter in any case, because the same advantages can not be realized. In fact, it is first necessary to melt the matte in a reverberatory furnace, an operation which is always more costly than the simple and rapid melting in a cupola. Secondly, the great economy of the converter is the result of the utilization of the heat produced by the combustion of the sulphur, iron, and other elements more readily oxidized than copper. This saving in cost is not only not realized in the reverberatory furnace, but the use of fuel to maintain the temperature of the bath of matte constantly cooled by the blast striking it is a source of expense. Thirdly, while the operation in the converter lasts from 25 to 30 minutes, it will be much longer in the reverberatory. In fact, instead of going on simultaneously throughout the mass, the oxidation is effected only on the surface, gradually penetrating farther. From time to time, the slag must be removed, to clear the bath, resulting in a loss of time and in the formation of cinder rich in copper—a natural consequence of the method of removing it. Whatever precautions may be taken, the scorification of a large quantity of iron will rapidly wear the reverberatory furnace, causing increased expense for maintenance, and numerous interruptions in the work.

These troubles are not encountered in my process: the operation is rapid, requires only the fuel necessary to melt the matte in the cupola, and yields cinder melted at a high temperature and low in copper. The wear of the lining of the converter is small, and it can be easily repaired without interrupting the work. During two years of work, we have not missed an operation as the result of an accident of this kind.

I do not want to enter into the controversy in which Messrs. Howe, Johnsson, and Raht have been engaged. I will simply answer this: As to the question of using the converter in the metallurgy of copper, it is certain that, for more than fifteen years, a number of persons have had the idea, some of whom have made experiments, Mr. Hollway apparently having been the one who has paid most attention to it. He aimed at utilizing the heat generated to melt fresh charges of ore and to carry the concentration of the matte to a certain point. But he could not produce metallic copper. Briefly, no one has been able before myself to apply this idea and obtain practical industrial results. Like many others, I have had the idea, I have worked, studied, and have built a plant necessary to carry out needed trials; and I have established the practical working of the method. I am producing daily, by treating matte in the

converter, in the converter alone, large quantities of black copper running from 98 to 99 per cent. I hold that the true author of a process is the one who, seizing an idea, often well known, studies it, and by his labor succeeds in transforming it into a practical method, yielding good results and realizing an important economical progress.

RUE CHILDEBERT 1, LYONS, May 17, 1883. PIERRE MANHES.

Mechanical Roasters.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Mr. E. Gybbon Spilsbury, in a paper on Gold Mining in South Carolina, read at the Roanoke Meeting of the American Institute of Mining Engineers, and printed in your issue of June 23d, after commenting on the virtues and defects of a mechanical roasting-furnace in operation at the reduction-works of the Haile mine, makes the following statement: "Like all mechanical roasters, however, this furnace can not be relied on for perfectly uniform results; and until this and other mechanical difficulties have been obviated, I have fallen back on the old-fashioned but always reliable 'Fortschaufelungs' furnace." He then states that labor in South Carolina is 90 cents per day, and fuel less than $1 per cord, delivered; that a double-hearth furnace, of 8 tons' daily capacity (for concentrated gold-bearing sulphurets), cost only $800 to build; finally, that the cost of oxidizing roasting does not exceed $1.10 per ton.

If Mr. Spilsbury has never succeeded in constructing a mechanical roaster which gives uniform and reliable results, and if he has been so unfortunate as never to operate with one which works satisfactorily, he should not condemn, in a general way, all mechanical roasters. Of all engineers, the members of the American Institute should be progressive and well-informed. What would become of our American mining industry if we were to follow Mr. Spilbury's advice in other departments, and return to devices of a hundred years ago?

Having had especial experience in roasting, I consider it a duty to take up this question of "mechanical roasters" for the benefit of those interested in mining, who might be easily misled by the statement of an engineer so favorably known as Mr. Spilsbury.

It is a fallacy to suppose that the reverberatory furnace can be relied upon for perfectly uniform results. The latter depend entirely upon the individual skill and the fidelity of the laborer in performing his task. With our ever-fluctuating population in mining camps, it is difficult to keep a large force of men for an indefinite period at the same work, and it requires more skill and more judgment to roast a charge successfully in a reverberatory furnace than in a well-constructed mechanical furnace. Even in old-established metallurgical works in Europe, where the son inherits the trade of the father, the results of reverberatory furnace roasting are by no means entirely uniform. At the Mansfeld Copper-Works, the residues from the Ziervogel process are returned for a second roasting if they contain above 0·023 per cent of silver. In roasting zinc-blende, for the manufacture of zinc, the roasters are fined if they leave a certain percentage of sulphur in the charge, and receive a premium if they do better than the permissible margin.

When the Manhattan mill, at Austin, Nevada, abandoned roasting in reverberatory furnaces, and adopted the Stetefeldt furnace, Mr. Allen A. Curtis, the superintendent of the company, stated to me in a letter of October 6th, 1870: "August workings, as compared with the average of 1869 (using reverberatory furnaces), show a saving in cost of reduction of $12.75 per ton of ore. The percentage of silver extracted was 4·72 per cent more than the average of the year 1869."

The first progressive step in the construction of roasting-furnaces was made by William Brückner, in the furnace which bears his name. Here the "rabbler" is discharged; but the necessity of nicely regulating the fire at different stages of the process, and the judgment required to decide when the charge is finished, remain. But the roaster who knows how to treat a charge in a reverberatory furnace will certainly do better in a Brückner, because he is rid of the heavy manual labor, and can pay more attention to his fire. That the Brückner furnace can do, and has done, as good work as the reverberatory furnace, and better, and this with greater economy, Mr. Spilsbury will not deny. I have, at this moment, no statistics at hand to prove this.

The next progressive step in roasting, on this side of the Atlantic, was made by the writer, in inventing the Stetefeldt furnace. In this furnace we not only get rid of the "rabbler," but maintain a uniform condition throughout, which, however, can vary between certain limits. Hence, the fireman is called upon to exercise but a small amount of judgment. In practice, I have never failed to take a "green" laborer of average intelligence, and teach him how to fire a Stetefeldt furnace to perfection in less time than a week. It is not possible to make the same man a perfect roaster on a reverberatory furnace in so short a time.

Most other "mechanical roasters" used in this country, which work on the continuous principle, partake of the construction of the Brückner and Stetefeldt furnaces, but present no essentially new features, even if they differ materially in outward appearance.

I will now give numerous statistics as to the working of the Stetefeldt furnace, which prove that the results, far from being unreliable and lacking uniformity, are rather remarkable for their regularity and small deviations from average figures, especially so if we consider the varying character of the ores treated. In all the following statistics, decimals are omitted for the sake of brevity, and only given in monthly averages.

Surprise Valley mill, Panamint, Cal. Chlorination-tests made from September 19th to October 23d, 1875; certified by C. Weberling, assayer and superintendent.

In 96 samples, we find that the following percentages of chlorinations occur:

85 per cent.	1 time.	92 per cent.	18 times.
87 "	1 "	93 "	24 "
89 "	1 "	94 "	26 "
90 "	3 times.	95 "	12 "
91 "	7 "	96 "	3 "

The two low samples of 85 and 87 per cent were caused by having a new laborer on the furnace, who had never fired it before, the regular fireman failing to be on shift.

Manhattan mill, Austin, Nev. Chlorination-tests made from November 1st to December 24th, 1877; certified by F. E. House, assayer.

In 198 samples, we find that the following percentages of chlorinations occur:

88 per cent.	7 times	92 per cent.	28 times.
89 "	28 "	93 "	15 "
90 "	49 "	94 "	— "
91 "	68 "	95 "	3 "

The same mill. Monthly averages of chlorination-tests from October 1st, 1874, to September 30, 1875; obtained from Alexander Trippel.

1874. Oct.	90·3 per cent.	1875. April	90·8 per cent.
Nov.	89·2 "	May	91·6 "
Dec.	91·1 "	June	92·8 "
1875. Jan.	89·8 "	July	92·3 "
Feb.	90·0 "	Aug.	91·8 "
March.	90·6 "	Sept.	91·5 "

Ontario mill, Park City, Utah Ter. Chlorination-tests during July, 1881; copied from the assay-book; Joseph E. Galigher, superintendent of the mill; C. W. Watkis, assayer.

In 58 samples, we find the following percentages of chlorinations to occur:

88 per cent.	1 time.	92 per cent.	13 times.
89 "	1 "	93 "	21 "
90 "	2 times.	94 "	9 "
90 "	8 "	95 "	3 "

The same mill. Average chlorination-tests from March to September, 1882, according to Russell's method; furnished by E. H. Russell, assayer:

1882. March	92·0 per cent.	1882. July	93·0 per cent.
April	91·3 "	Aug.	92·2 "
May	92·9 "	Sept.	91·4 "
June	92·5 "		

The same mill. Chlorination-tests, according to Russell's method, from October 12th, 1882, to January 1st, 1883; furnished by E. H. Russell, assayer.

In 131 samples, we find the following percentages of chlorinations to occur:

87 per cent.	1 time.	93 per cent.	46 times.
90 "	2 times.	94 "	33 "
91 "	10 "	95 "	9 "
92 "	30 "		

Lexington mill, Butte City, Mont. Ter. A. Wartenweiler, superintendent; G. C. Carson, assayer. Official report.

The Lexington ore contains more or less native silver; hence the results of amalgamation are a better standard for the furnace work than chlorination-tests:

Month.	Furnace.	Chlorination. Per cent.	Left in tailings. Per cent.
December, 1882	No. 1.	82·9	10·0
" "	No. 2.	85·1	11·8
January, 1883	No. 1.	85·9	9·9
" "	No. 2.	85·9	10·8
February, "	No. 1.	86·9	7·4
" "	No. 2.	86·0	8·5
March, "	No. 1.	89·9	7·8
" "	No. 2.	90·1	8.9
April, "	No. 1.	92·6	6·1
" "	No. 2.	92·5	6·5
May, "	No. 1.	93·8	5·5
" "	No. 2.	94·6	5·3

Here we observe a gradual and marked improvement in results, which is, in part, due to a change in the character of the ore, and to Mr. Wartenweiler's skillful management.

At the Auburn mill, Reno, Nev., I have roasted (oxidizing) gold-bearing sulphurets from the Meadow Lake mines with perfect success. The pyrites were completely converted into red peroxide of iron, no magnetite was formed, and no iron sulphate left undecomposed, while the gold was bright (showing itself to be so by panning out a sample of roasted ore), and amalgamated without difficulty by the ordinary pan process.

A small Stetefeldt furnace was also run near Kernville, Cal., on gold-bearing pyrites exclusively, and the gold extracted by pan amalgamation to the entire satisfaction of the owners of the mill. The statistics I have not at hand.

These statements are certainly sufficient to refute Mr. Spilsbury's wholesale condemnation of "mechanical roasters."

But we have another question to discuss, namely, that of economy. Mr. Spilsbury's figure of $800 for constructing a "Fortschaufelungs" furnace with double hearth, 40 feet by 5 feet, seems to me rather low, even if he does not include the chimney. To be rightly understood: I do not doubt the correctness of his statement for a moment; but I hesitate to believe that a first-class and durable double-hearth furnace can be built at such a low figure. And even well-constructed furnaces of this kind are expensive in repairs. For this reason, the double-hearth "Fortschaufelungsofen" has been abandoned in Freiberg, and single-hearth furnaces have taken its place. But we will leave the question of repairs entirely out of consideration, and only speak about first cost of construction. A well-constructed Stetefeldt furnace, with dust-chambers and chimney, of 24 tons' daily capacity, equal to three "Fortschaufelungs" furnaces, can certainly be erected in South Carolina for $8000. We will add to this a nominal royalty of $2500, which would be accepted by the Stetefeldt Furnace Company in such a case. Total cost of furnace, $10,500, or $8100 more than three "Fortschaufelungs" furnaces of Mr. Spilsbury's design. Calculating on this amount interest and amortization at 12 per cent per annum, we have $972. Running the works with 24 tons' daily capacity only 300 days in the year, this interest will increase the expense of roasting in the Stetefeldt furnace 13½ cents per ton.

To roast 24 tons of gold-bearing sulphurets in a Stetefeldt furnace would require 4 cords of wood, 3 firemen (one per 8-hour shift), and 4 men for discharging (two per 12-hour shift). Hence we have cost of roasting 24 tons:

4 cords wood, at $1	$4.00
7 laborers, at 90 cents	6.30
Screens and tools	0.75
	$11.05
Fuel and labor per ton	$0.46
Interest	0.13½
Total per ton	$0.59½

According to Mr. Spilsbury's estimate, his cost of roasting is $1.10 per

Digitized by Google

ton. Difference in favor of the Stetefeldt furnace, 50½ cents per ton, or, on a production of 7200 tons per year, a net saving of $3636. Hence the Stetefeldt furnace would pay for itself in a very short time. In this calculation, we have taken no account of difference in cost of repairs, which is largely in favor of the Stetefeldt furnace.

A Stetefeldt furnace of less capacity would not be so profitable, but would still leave a considerable margin in its favor. C. A. STETEFELDT.

24 CLIFF STREET, NEW YORK.

OFFICIAL STATEMENTS AND REPORTS.

COPPER QUEEN MINING COMPANY, BISBEE, ARIZONA.

The second published annual report of this famous mine is somewhat meager. During the year ended March 31st, 1883, 32,942 tons of ore were extracted, 14,886 tons being taken from the 1st level and the open cut, 12,809 tons from the 2d level, 5119 tons from the 300-foot level, and 127 tons from the west end workings. The second level has proved to be all that was expected of it, and Mr. B. Williams, the superintendent, estimates that he has still there reserves amounting to 20,000 tons. Developments below the 300 level have been checked by the heavy influx of water. The incline is sinking in the limestone. During the year, $25,480.46 were paid out for two large new boilers and a hoisting-engine, which will enable a depth of 1000 feet to be reached. For toll-roads, $22,832.63 were paid, and Mr. Williams estimates that, based on last year's transportation, the saving is equal to $34,000. During the year, 33,029 tons of ore, averaging 12·73 per cent of copper, were smelted with 5687 tons of coke, and the consumption of 3125 cords of wood, producing 8,409,112 pounds of black copper running 96½ per cent fine. The total cost of mining, freight, construction, refining, and administration was $761,071.13, or 9·05 cents per pound of black copper. The returns for the sale of black and ingot copper in New York were $1,363,508.72, the net value of the year's product being $1,314,973.25, leaving a profit of $553,902.12, out of which four dividends, aggregating $475,000, were paid, leaving $78,902.12 to be added to the surplus account, which, at the end of the second fiscal year, amounted to $267,028.51.

THE CLEVELAND MEETING OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Thursday was occupied almost entirely by excursion visits to various industrial establishments in the vicinity of Cleveland, following one another in such rapid succession that the zeal of the most enthusiastic began to flag before the day's journey was ended. On a special train, provided by the Pennsylvania Railroad, the engineers were taken first to the works of the Otis Iron and Steel Company, of which Mr. S. T. Wellman is superintendent and general manager, and under whose skillful care the works have developed into the model open-hearth plant and steel plate and axle works of the country. We shall take an early opportunity to describe the works in greater detail; and must only say now that on every hand the engineers met the evidences of a progressive spirit and of long experience.

A short ride brought the party to the works of the Cleveland City Forge and Iron Company, of which Mr. L. M. Coe is vice-president and manager. In one large building, there are fourteen helve hammers in a row, each facing its re-heating furnace, and a battery of two steam-boilers. The principal work done is the forging of car and locomotive driving-wheel axles and shafts, the largest forging of the kind which the works are capable of handling being 26 inches in diameter. A special department of the works is an annex in which coupling-pins and links are made by machinery.

Adjoining these works are the shops of the Cummer Engine Company, of which Mr. F. D. Cummer is vice-president, and William M. Barr is engineer and superintendent. The works are well stocked with modern machine tools, and we understood that special machinery was building to turn out the Cummer engine, the specialty of the works. The engineers carefully examined the work on hand, and the general verdict was a very complimentary one to the company as to carefulness and accuracy of workmanship. The machinery of the shop is driven by a Cummer engine, built at Detroit, and ample opportunity was given to note how closely the automatic cut-off adapted itself to variations. We shall, at an early date, refer more in detail to the latest design of the engine which the company has just begun to build.

The next place visited was the establishment of the Union Screw Company, one of the wonders of which Cleveland is particularly proud. In a building of noble dimensions, are hundreds of machines which automatically first cut wire into lengths and forge a head, then shape and slit it, and finally cut the thread, simultaneously putting a taper into the screw. During the entire process of manufacture, the metal is not touched by hand, the only labor, that of girls entirely, being to keep the machines supplied with raw material, and remove the finished product.

Again entering the train, the party was taken to the large works of the Brush Electric Company, splendidly equipped to manufacture the dynamo-electric machines and the lamps now known in almost every city of the country, which are the invention of Charles Brush, the electrician. Unfortunately, the time at the disposal of the visitors was limited, and the hour being noon, the machinery was not in motion.

At the works of Messrs. Warner & Swasey, was shown the running gear of the dome of the McCormick Observatory for the University of Virginia, the great object being to diminish the friction. With a load of ten tons, the weight of the dome, a force of 30 pounds, applied at the circumference, is sufficient to keep in motion at the desired speed. The dome is 35 feet in diameter, the weight being carried by a circular plate resting on nineteen central wheels, while two outer wheels for each of the latter roll on a flat circular track. Another object of interest at the works of Messrs. Warner & Swasey was a horizontal straight-line engine, designed by Prof. John E. Sweet, of Syracuse, N. Y.

At the Cleveland Malleable Iron-Works, to which the party next went, some time was spent in examining the methods of making malleable iron. The pig is partially refined to white iron in reverberatories, having a roof removable in sections. There were at the works two long rows of annealing furnaces, and the usual accessories of such a plant. We may here add that a firm at Newark, Ohio, has succeeded in constructing a furnace in which the castings are packed in bulk, the expense of the iron boxes, which wear rapidly, being thus avoided.

The enormous establishment of the Cleveland Rolling-Mill Company was then hurriedly walked through, the departments visited being the sheet mill, open-hearth plant, Bessemer steel mill, wire mill, and merchant mill.

We are indebted to Mr. William Chisolm, President, for the following notes on these works: There are four furnaces, 65 feet high and with 16-foot bosh, having each a capacity of 400 tons per day. They use Connellsville coke and Brier Hill, O., coal and Lake Superior ores from the mines of the company, blast being furnished by nine blowing-engines. The puddling-mill has 24 single furnaces with a daily capacity of 50 tons. In the merchant mill, there are four trains with a capacity of 200 tons per day, and in the sheet and plate mill five trains with a capacity of 75 tons per day. In the wire-rod mill, there are three trains capable of working 150 tons per day. One of these trains, which attracted very much attention, being considered one of the best of its kind in the country, can roll 100 tons of No. 5 rods per day of twenty-four hours, and has rolled rods from a four-inch billet 3000 feet long. The open-hearth plant consists of five furnaces, of which three are ten-ton and two twenty-ton furnaces. The best week's record of the open-hearth plant has been 1000 tons. The ingots are cogged in a two-high reversing blooming train, designed and built by the Cleveland Rolling-Mill Company. It has 38-inch rolls, the usual speed being 40 revolutions. The engines have 40-inch cylinders and a 4-foot stroke. The daily capacity of the train is 750 tons, and it can roll 7-inch square ingots down to 1¼-inch square billets. The latter are principally used for wire. The Bessemer plant consists of two converters with an annual capacity of 150,000 tons of ingots, the best record of the rail mill, which the visitors did not see, being 1752 tons of rails of 60 pounds per yard section. The works employ 5800 men, have a monthly pay-roll of $250,000, and use daily 1500 tons of coal. The other part of the works shown had comparatively little that was novel or interesting, most of the machinery and furnaces being of an ancient type.

After discussing a lunch at Dean's Hall, near the works, the party took a train, and was carried off to the Central Works, at which the new blast-furnace, No. 5, of the Cleveland Rolling-Mill, was inspected. We are indebted to the kindness of Mr. Hugh Watson, superintendent, for the following details:

Furnace No. 5 has a total hight of 75 feet, and a 20-foot bosh. Blast, heated to an average of 1200 degrees Fahrenheit, in three Whitwell hot-blast stoves, 68 feet high and 21 feet in diameter, is blown through 8 tuyeres at the rate of about 30,000 cubic feet per minute at a pressure of 8 pounds. The two blowing-engines built by the Cuyahoga Steam Furnace Company, of Cleveland, are vertical, with a 38-inch steam-cylinder, an 84-inch blowing-cylinder, and 4½-foot stroke. They are reported to be doing their work very well, and were much admired by the visitors. Steam is provided by 16 boilers, 46 inches in diameter, 34 feet long, and with two flues, 16 inches in diameter. The hoist was built by Crane Brothers, of Chicago, and has a 14 by 18 inch steam cylinder, link motion, and a 5-foot drum. The ores used at this furnace are exclusively from Lake Superior, the mixture being 12½ per cent of magnetic, 12½ per cent of specular, and 75 per cent of hematite, the fuel being Connellsville coke. The average charge is 6600 pounds of fuel, 9900 pounds of ore, running 58 per cent of iron, and 3660 pounds of limestone. The average product of the furnace is 1400 tons weekly of No. 1 and No. 2 Foundry, the best record made since the furnace was blown out in February of the present year being as follows: Best day, 251 tons (at 2268 pounds) and 2052 pounds; best week, 1526 tons; and best month, 6206 tons. The furnace is admirably located for the receipt of raw materials and the shipment of product, and all its appointments are first-class.

The engineers, who had by this time a tired look, were carried off by their hosts to the city water-works. The capacity of the pumping-engines in twenty-four hours is as follows:

1 pair	Cornish pumping-engines	8,000,000 gallons.
1 "	Worthington compound duplex engines	10,000,000 "
1 "	Henderson " " "	10,000,000 "
1 "	Worthington " " "	10,000,000 "

A new storage reservoir is building in the eastern part of the city, which will have a capacity of 70,000,000 gallons. The lake tunnel through which the supply of water is drawn is 5 feet in diameter, 1¼ miles long, of which 1¼ miles are under the lake.

In going to the water-works, the party passed along the famous ore-docks of Cleveland, on which thousands and thousands of tons of ore were piled awaiting purchasers—a suggestive proof of the stagnation in the iron trade. During 1882, the receipts of iron ore at Cleveland were 1,686,000 tons, which thus far have been handled in a very crude way. Efforts are vigorously making to improve it, and among the most prominent of recent devices is that of Mr. Alexander E. Brown, which is capable of covering a very large field of utility elsewhere, in our immense docks and yards. The Brown hoisting apparatus was shown in operation; but as we propose to give it fuller attention in the near future, we need not refer to it at length here.

The tired and dusty party again got into the train and was carried back to Cleveland, with time enough on their hands to prepare for

THE FINAL SESSION,

which was held in the evening at the rooms of the Vocal Society. The first paper read was by Oberlin Smith, of Bridgeton, N. J., on Spiral Springs. After a general summary as to the value and characteristics of the various classes of springs, Mr. Smith gave the results of a series of over 200 experiments on various materials, including hard brass, soft and tempered steel, iron, phosphor-bronze, etc. The discussion which followed indicated that a number of gentlemen were inclined, from experience, to challenge some of Mr. Smith's conclusions, while others spoke in reference to the formulæ existing as to the capacity of springs.

Gustavus C. Henning, of Pittsburg, then, in a paper entitled Some Notes on Steel, gave some very interesting facts developed in testing the

Digitized by Google

steel eye-bars and girders made at the Keystone Bridge-Works, detailing the different methods of manufacturing eye-bars, and submitting data in reference to punching and drilling steel plates. Mr. Henning showed a tracing of a steel plate which had suffered accidental injury. In the efforts made to restore it to its original shape, instructive lines of weakness were developed. Mr. Henning is an enthusiast on the subject of steel for structural purposes, and states that steel is 10 per cent cheaper than iron when proportions are based upon equal strength of the structure made of both materials.

Mr. W. F. Durfee then read a paper on Machinery for Maneuvering Clutch Couplings, to which we shall refer at an early date at length. The following papers were then read by title: Economy in Subdivision, in Installation and Operation of Machinery at Varying Demand, by J. L. Horning, of Jersey City; Ingot Cranes, by Gram Curtis, of New York; On a New Method of Constructing a Crank-Shaft, by J. E. Sweet, of Syracuse, N. Y.; Note on the Water-Hammer in Steam-Pipes, by R. H. Thurston, of Hoboken, N. J.; A New Form of Balance Dynamometer, by S. S. Webber, of Lawrence, Mass.; Some of the Mechanism Employed in Multiplex Telegraphy, by T. W. Rae, of New York; On a New Method of Casting Flange Pipe, by J. E. Sweet, of Syracuse; and Note on the Effect of Prolonged Stress on Iron, by Robert H. Thurston.

After passing a series of resolutions of thanks to those to whom the society was indebted for courtesies extended, the meeting adjourned.

MINERS' SAFETY-LAMPS.*

By J. B. Marsaut.

In an elaborate essay by the engineer-in-chief of the Bessèges collieries, Gard, in the south of France, this important subject is investigated with characteristic care, thoroughness, and discriminating fairness. Belgium having in 1864 decreed the use of a standard pattern of the Mueseler safety-lamp for her deep and fiery coal-pits, the same lamp has come into extensive use in France also, after having there undergone a series of experiments at the hands of Messrs. Mallard and Le Chatelier, on behalf of the French Fire-Damp Commission. The Belgian Mueseler, which has the usual internal funnel or taper chimney of solid sheet-metal, supported above the wick by a horizontal annular diaphragm of wire-gauze, is subject to the serious inconvenience of going out when tilted; its usefulness is thereby greatly curtailed, particularly where there is any haulage on inclined planes. Ten years ago, Mr. Marsaut's own experiments led him to modify the Mueseler lamp, by discarding the diaphragm while retaining the chimney; a sheet-iron casing was also added outside the gauze cylinder, to prevent flame from passing outward through it when exposed to a current of fire-damp; and a movable ring was fitted around the circle of the air-inlets, for closing them all simultaneously, so as to extinguish the lamp. This lamp does not go out when tilted; does go out in fire-damp; and does not let flame pass outward, even when exposed to strong currents of fire-damp in any direction. The only inconvenience noted by the French Fire-Damp Commission, when recording† their high commendation of the lamp, was, that the sheet-iron casing prevents its being seen at a glance whether the lamp is all in proper order inside it.

Renewing his efforts at improvement, the author lately entered upon a further extensive series of experiments at Bessèges, of which a detailed account is given. Excellent drawings are furnished of the numerous safety-lamps tried, of which the following is a bare enumeration, all being examined and commented upon in detail as to their respective merits and demerits: the Mueseler, of Belgian and of English pattern, with several other varieties; the original Marsaut lamp of 1871, and several varieties of its present improved construction; the Davy, of Newcastle, Gard, and Dubrulle patterns, the fire-trier's, and the "tin-can;" the Stephenson, Williamson, Clanny, Bainbridge, Evan Thomas, Upton & Roberts, Birckel, Boty, Westphalian under two forms, Rosenkrantz, Combes, and Cosset-Dubrulle. Tabulated statements are given of the results obtained in the author's trials of the various lamps; in his specially elaborate trials of the Mueseler and Marsaut lamps; in his experiments upon the resistance of wire-gauze to the passage of flame, and upon the influence of the dimensions and shape of the gauze itself; and in trials of the comparative lighting powers of the different lamps.

The practical conclusions derived from these experiments are summarized as follows. With the large Davy lamp used in the Gard District, and with other lamps of the same kind, an explosive still atmosphere outside is fired by an explosion inside the lamp. The addition of a second gauze cylinder to these lamps diminishes considerably the frequency of outside explosions, but is powerless to prevent them. The flame seems to pass out through the cap of the gauze cylinder, rather than elsewhere; whence it is well to add another layer or two of gauze at this weak part. The outside atmosphere is more readily fired by explosion within a lamp in which the wick is burning low; the prevalent practice of lowering the wick on encountering fire-damp is consequently objectionable; it is better to remove the lamp slowly, keeping the wick at its usual hight. Large lamps are more dangerous than small ones, because the volume of explosive mixture they contain increases as the cube of their size, while the area of gauze or of outlet for the flame to pass through increases as the square only. The glass cylinder in the Mueseler and other lamps, though giving a better light, renders the explosions inside more violent, because the explosive mixture is thereby more confined, so that the lamp becomes a sort of miniature cannon; the glass should therefore be kept as small as possible, particularly in hight. The Belgian Mueseler, considered the safest lamp in use hitherto, sometimes explodes a still atmosphere of fire-damp outside it. Lamps with glasses are dangerous when the wick burns low, for the same reason as the Davy; in the Mueseler particularly, the flame can then more readily pass up through the chimney, and so get to the upper side of the gauze diaphragm. The plan long in vogue at Bessèges, of ascertaining the presence of fire-damp by measuring the elongation of the lamp's full flame, is safer than reducing the flame to the utmost for the purpose of seeing the blue cap of gas better; the elongation of the flame is almost always a sufficient indication. When a glass lamp is lifted up into an explosive atmosphere, it should be held there steadily till it goes out, especially in the case of lamps having their air-inlet at top: instead of being immediately withdrawn again, as would intuitively be done either through fear or to keep it alight; for a downward movement seems to have the effect of churning the gas inside the gauze, and so rendering its explosion more violent and thereby more dangerous. As soon as ever the gas burns very visibly in a lamp, and shows its characteristic tuft of flame, there is no fear of internal explosion occurring. It is particularly dangerous for a lamp to get suddenly filled with explosive mixture by a current blowing the flame against one side, or for the lamp itself to be tilted in such an atmosphere: any arrangement for checking undue access of gas to the lamp is a safeguard. The whole of the air-inlets should be protected by a least a double layer of wire-gauze, even in the Mueseler lamp with its chimney, which latter does not always isolate the flame; then, if the inner gauze ever gets red-hot, the outer still serves as a protection. The confined space inside a lamp should be kept as small as possible; but the gauze, which cools down the gases passing out through it when the lamp explodes inside, should present as large an extent of surface as can be; hence lamps are not to be relied on which have a tall glass surmounted by a dwarf gauze, such as the big Cosset-Dubrulle, the Bainbridge, and others like them. Lamps should be made of as small diameter as possible, and should carry as large a flame as they can without getting too hot; the aim should be to make a lamp behave as much as possible like a mere chimney. In glass lamps with air-inlet at top, the wick-holder should be tall enough to raise the flame as high as can be inside the glass; a neutral space is thus left in the bottom of the lamp, whereby the force of an explosion within the lamp is mitigated. A chimney in a lamp is attended with more or less risk. The slightest modification in form or arrangement of a lamp may make a considerable difference in its safety.

Marsaut Safety-Lamp.—In its present improved form, this lamp has a strong glass cylinder, 2·44 inches high, 1·65 inches inside diameter, and 0·31 inch thick, secured in a protecting cage on the top of the oil reservoir, as in the Mueseler lamp; but the Mueseler chimney, and the gauze diaphragm that carries it, are done away with. Surmounting the glass cylinder, and flush with its inside circumference, is an inner gauze cylinder, 4 inches high, tapering slightly smaller upward, and closed at the top by a gauze diaphragm. An outer gauze cylinder, about ¼ inch larger in diameter, ⅜ inch taller, and similarly closed at top, incases the inner gauze; and is fixed at the bottom into the copper ring that forms the upper rim of the cage holding the glass. The mesh of the gauze is nine hundred and thirty holes per square inch, or thirty and a half per lineal inch. The entire gauze is shielded by an external sheet-iron casing, which can be lifted off at pleasure, having inlet holes around the bottom for the air to enter the lamp, and outlet apertures at the top.

While the general shape and construction of the Mueseler lamp, as sanctioned by practice, are thus preserved in the Marsaut, the small horizontal annular diaphragm of gauze supporting the chimney in the former is replaced in the latter by the inner gauze cylinder, which presents a far larger cooling surface for the hot gases inside the lamp to pass out through. Additional safety can be secured by further covering the flat top of the inner gauze cylinder with a gauze hood, so as to double the thickness of gauze at that part, upon which the force of an explosion inside the lamp comes most directly. A third complete cylinder of gauze may even be added, if desired as an extra precaution; but two are considered safe enough by the author, and preferable generally.

The advantages of the Marsaut lamp are, that it seldom goes out when tilted, and not at all in an upward current of air, nor does it explode externally a strong current of gas blowing upon it in any direction whatever. It does not fire an explosive still mixture of air and lighting-gas, as has been proved by upward of twelve thousand trials at Bessèges, when most of the other lamps in use did so, the Belgian Mueseler included. The outside casing effectually protects the gauze from getting injured, clogged with dust, or splashed; and whenever the lamp explodes inside, the casing retards the escape of the burnt gases, which thus help to put the lamp out. By simply covering with the hand the inlet or outlet holes in the casing, the lamp can readily be put out whenever desired.

In the trials made of the Marsaut lamp at Bessèges, an explosive mixture was employed of air and of lighting-gas, which latter fires more readily than fire-damp; and the wick being reduced below its usual flame, the conditions were thus more trying than are met with underground. With three forms of the Marsaut lamp, testing two lamps of each form, upward of six thousand trials failed to produce a single external explosion; whereas fifteen Belgian Mueselers, tested simultaneously, each of them about a hundred times over, let the flame pass through the horizontal gauze diaphragm in 31 per cent of the trials, and in 2½ per cent produced explosion outside the lamp.

Still severer trials were also made, by mixing air with lighting-gas in their most highly explosive proportions, namely, 100 volumes of air to 20 volumes of gas, and exploding the still mixture inside the lamps by an electric spark. Under this excessive test, the large Davy lamp used in the Gard District exploded the mixture outside it every time; the Boty, Clanny, and Belgian Mueseler, and the Marsaut lamp with two gauze cylinders, almost every time; but twelve trials of the Marsaut with three gauzes, and ten of the fire-trier's Davy, gave not a single explosion outside. These tests, and the one preceding, point unmistakably to the desirability of reducing to the utmost both the total internal volume of a safety-lamp, and also the hight of the glass, since the blind space inclosed by the glass acts like a cannon in propelling the inside explosion violently against the gauze, and so driving the flame out through it. How great an effect has the hight of the wick in the glass was proved by these experiments, a variation of less than 0·4 in the Boty lamp being sufficient to produce or prevent explosion outside. The trials also show that the Davy of small diameter, still used in England by the fire-trier, but abandoned in the Anzin and Bessèges collieries, presents important advantages, and, if sufficiently protected against strong currents, would possess a high degree of safety. They further demonstrate that the electric spark is essentially dangerous in fiery mines; which should be borne in mind in any attempts to introduce electric lighting in colliery workings.

Investigating experimentally the mesh and shape of the wire-gauze cylinder, the author concludes that, for the same total area of apertures

* Translated and abstracted by Alfred Bache, B.A., Assoc. Inst. C.E. Published in Selected Papers of the British Institution of Civil Engineers.

† Commission du Grisou, Paris, Minutes of Meeting of March 8th, 1882.

Digitized by Google

per square inch, gauze of finer mesh is safer than a coarser and heavier make. The lamp should be made inside as nearly cylindrical as possible throughout its entire hight; and in particular the bottom of the gauze should be flush with the inner circumference of the glass. Any narrowing at this part, by the insertion of a horizontal annular diaphragm projecting inward, or by contracting the gauze cylinder to a smaller diameter than the glass, is objectionable; doubtless because the explosive mixture inside the lamp gets thereby so churned up as to augment enormously the rapidity with which it explodes, enabling the flame consequently to pass out through the gauze.

The comparative lighting power of the various lamps tried by the author was found to be as follows:

ENGLISH* STANDARD CANDLE, 100.

1. Westphalian.....77	8. Mueseler, Belgian 49
2. Boty.....72	9. " English.....44
3. Westphalian.....70	10. Bainbridge.....39
4. Marsaut.....69	11. Davy, Dubrulle.....32
5. Williamson.....56	12. " Gard.....22
6. Thomas.....53	13. " Newcastle.....20
7. Clanny.....52	14. Stephenson.....17

In the Westphalian lamps, Nos. 1 and 3, the air inlet is through a collar of perforated sheet-iron all around the neck, below the bottom of the glass; No. 3 was protected by the addition of a layer of wire-gauze inside the perforated collar; but No. 1 was without this protection.

The lighting power seems to depend partly upon the metal of which the lamps are made, a brass lamp being found to give only 70 per cent of the light obtained from the same make in wrought-iron. The difference is no doubt connected with heat-conducting capacity. English lamps are generally made of brass, and German of wrought-iron. Mr. Marsaut is inclined to think steel, or perhaps malleable cast iron, would be advantageous.

THE LAKE COPPER INTERESTS.

Special Correspondence of the Engineering and Mining Journal.

The announcement that the Osceola would divide but fifty cents per share among the stockholders on the 2d proximo, instead of its usual dividend of one dollar, is another unmistakable evidence that American copper has entered on at least a transient career of hard times. This mine has never made any bluster or pretension, has avoided every thing that looked like fiction or puff-paste, and as a result it has been regarded for years as among the most trustworthy properties of all our Michigan mines. No mine now furnishes a better thermometer for judging the real condition of the market; for it illustrates what returns a mine can make, even though the percentage of copper be very very small, when the property is managed by brains. Several circumstances make the Osceola the representative mine: first, its yield per cent is as low as or lower than the average lodes; second, while the Quincy has been the foot-ball of speculation, the Pewabic alternately tossed by the bulls and hugged by the bears, according as that far-famed mirage of striking the Quincy bonanza has appeared and vanished; while the Franklin has suffered from domestic broils, and the Central has been out of the market, and the Allouez just getting out of the woods, and the Atlantic ebbing in dry days and flowing as it came time for the division of profits, and the Calumet & Hecla, with its wondrous resources, has remained oblivious to all kinds of markets; the Osceola has gone on the intelligent, economical, and unpretending tenor of its way, neither going higher nor lower unless the market for ingot has shown the most unmistakable reasons for such a procedure. To see the dividends of this mine shrink fifty per cent, therefore, makes the speculator in copper securities pause and recast the forces which now control the market.

The question of supply was considered in my letter of the 2d instant, when your correspondent attempted to give the mines the benefit of the doubt in every case of uncertainty. The reports which are now coming up from the West, and the preparations now going on at the Calumet & Hecla stamps to increase its monthly product by nearly one quarter, are *prima-facie* evidence that my estimates were too low by many million pounds. However, they were large enough for all practical purposes, since they showed, what the grim logic of events is daily proving, that American copper has turned a new and dubious leaf in its history. Your correspondent thought to take up the foreign demand and the South American and Spanish resources for its cheap supply; but the recent sale of the large block of ingot to home consumers (reaching 26,000,000 pounds, the Hancock *Mining Journal* asserts, it says, on the highest authority, instead of 20,000,000 pounds, as given by the ENGINEERING AND MINING JOURNAL), at fifteen cents, with the agreement to maintain home prices until September at sixteen cents, gives us breathing space to turn our attention to a more important field, namely, *cost of production*. Here, of course, lies the rub. The shrewdest superintendents in Copperdom have told me that they have scrutinized over and over again their schedule of expenditures; pored over every item, re-examined every detail, in hopes of finding relief from the pressure of the year's markets. What they will accomplish, like Matthew Arnold's wave of fate, only events can tell us in their hour. The Phœnix closed down, or what amounts to the same thing, last week. This mine, like the Cliff, which also lately suspended operations, was a veteran, and has been famous for its huge masses of copper. Workmen are now engaged on a mass of considerable size, and the general underground appearance of the mine is by no means discouraging, only as present prices for mineral make operations burdensome.

The cost of copper mining depends principally upon—

I. Cost of labor.
II. Cost of supplies.
III. Cost of construction.
IV. Amount of barren ground encountered.

This last factor is always more or less uncertain, excepting, strangely enough, the two mines yielding one the largest and the other the smallest percentage of mineral of all our lodes, the Calumet & Hecla and the Atlantic. Neither of these mines is compelled to "open ahead," although the former has placed eight years' steady working behind its present active workings. The Atlantic does not "open ahead," in fact, could not do so through any barren ground at all and find its returns equal to its expenses. Its percentage of mineral is small, but its yield is regular and to be depended upon. It therefore sinks no winzes, but carries its stopes along with even pace with its sinking and drifting, thus moving its stopes more or less automatically. If this much-praised (and justly praised) property was compelled to go through such long and discouraging stretches of lean rock as the Pewabic, for instance, or the splendid Osceola, the Atlantic stockholders would sit by the rivers of Babylon and try to sing their songs of dividends in vain. The Atlantic, however, encounters no barren ground, but sends every thing through the stamps. The Franklin shows a decided tendency upward in its copper-bearing rock. The same is true of the Allouez, and, at present reports, of the Copper Falls, Peninsula, and, perhaps, the Pewabic. A comparison of the amount of discarded to hoisted rock, in an exhibit taken from the Osceola records, shows that the unproductive ground has been steadily gaining since 1879 at that property, although this is in a great measure due to exploring and other extraneous work. If, as I myself think, the year's work for 1883 should show as high an average yield of mineral per ton of rock hoisted and sent through the mill as was shown in 1880, the cost of producing a pound of copper would be reduced over one cent from present prices. If it reaches the yield both of productive ground and percentage of mineral given in 1879 (of which I do not pretend to be certain), the cost of production will be reduced nearly two cents per pound in this one direction alone. Of course, we can not see into the rock; but from what data there are at hand, it is quite certain that retrenchment will automatically set in along this line, not only in the Osceola, but also in many other of our lake mines.

III. *Construction Account.*—Construction, as a rule, will be particularly light this year. Outside of the railroad at the Conglomerate, the new locomotive at the Allouez, the new mills at the National, Conglomerate, and Peninsula, two heads at the Copper Falls, some improvements at the British and other mines in Ontonagon, and the usual tremendous outlay at the Calumet & Hecla, the aggregate construction account of Copperdom will not cut any remarkable figure in the year's expenditures. In times past, the introduction of improved hoisting-engines, air-compressors, power-drills, ball-heads in the mills, and improved facilities for treating large boulders at the rock-houses, has combined to swell the construction account into a very formidable proportion of the annual outlay. In some cases, it has reached nearly if not quite one fourth of the combined mining expenses. Nearly all of our mines are now well on their feet; the era of excessive expenditures for plants and mills has happily been passed; and they are able to cope with the events of a low market this year as never before. This summary is hopeful, therefore, in this, that it indicates first a decrease in construction expenditures, while it holds out, secondly, a confident hope of very increased returns in work accomplished.

II. *Cost of Supplies.*—Where the mines use coal for fuel, the cost of supplies about equals the cost of labor. Along the whole line of outgoes for supplies, retrenchment reasonably seems to be the order of the day. The general decline in manufactured iron will reduce the cost of supplies in this direction. I do not know as the manufacturers of machinery have as yet succumbed to the logic of the times; but such a course is inevitable, and not distant; for, in case the ironmongers should maintain prices at a notch which should help drive a large number of mines to the wall, a lack of buyers would glut the market with their wares, which is always sufficient, in the absence of combination and restriction, to disorganize and lower the market. There must also be a reduction in the price of coals. From what data there are at hand, it would seem to your correspondent as if we were on the threshold of a collapse in this industry. Whatever may be the condition of the anthracite market, and that forms no part of our present study, it is quite certain that the era of cheaper bituminous coal is very near at hand. Of course, it is impossible at this distance to keep one's finger on the pulse of the Pennsylvania and Maryland fields, and no pretension is made to infallibility of opinion; but the competition among carriers of soft coal has already proved an entering-wedge, and this, coupled with the cut in canal tolls by the Chesapeake people, and the struggle for business by the Cumberland mines, must split prices into smaller fragments. Lake people have always been willing to pay round prices for food, coals, iron supplies, and all items of construction; but, gentlemen, we can do so no longer. We must have lower prices or put our necks beneath the guillotine of bankruptcy. If prices come down, our people will do their level best to keep our mines from turning beam's end until the squall be over or we have adjusted our reckonings and outridden it into new ports.

These considerations lead us to infer that there will be a general movement of retrenchment through the whole list of expenditures, greater with some mines than others, but general and pronounced among all. If it should turn out that, in several of the mines on which attention is now fixed, the rock broken should show a better general average than last year; if the "construction account," which has eaten such holes in past revenues, can now be safely and generally dispensed with; and if the price of metal and fuel supplies comes down within reason, it is altogether probable that the cost of producing copper will be materially diminished this year. This should afford a good crumb of comfort to holders of discouraging properties, even if the comfort be only a mere crumb. It remains to study the wages problem, and then draw a general summary of the outlook of our individual mines. SPECULAR.

* The *bougie de l'Etoile*, frequently taken in French for the standard of lighting power, and so adopted by the author, is a stearine candle, of five to the pound, burning 9·6 grams per hour. The English standard is a sperm candle, of six to the pound, burning 120 grains per hour; it is found to give only 90 per cent of the light from the French *bougie de l'Etoile*. Hence the author's own percentages in this comparison are 0·9 of those here given, and range from 69 per cent for No. 1 down to 15 per cent for No. 14.

THE ENGLISH GUNPOWDER TRADE.—From the tables of imports and exports of gunpowder given in the appendix to the report of the Inspectors of Explosives, it is evident that the exports from Great Britain have been slowly declining during the last twelve years, the figures showing that while in 1870 154,979 cwt., valued at £427,229, were exported, only 126,604 cwt., worth £357,802, were sent out of the country in 1882. The importation, on the other hand, has been rapidly, though somewhat irregularly, increasing—mostly from Germany. In 1870, the total quantity received was 1187 cwt. valued at £6648. In 1882, the quantity imported was 9122 cwt., worth £37,180. England imported 1,008,050 pounds of dynamite during 1882.

NEW PUBLICATIONS.

THE RAILROAD SPIRAL. By WILLIAM H. SEARLES, C.E. New York : John Wiley & Sons. 1882. 12mo, vii+85 pages.

As a sequel to his well-known work *Field Engineering*, Mr. Searles has published the *Railroad Spiral*, in which he gives the theory of the compound transition curve, reducing it to a practical and convenient form for ordinary field-work. In an appendix, tables of deflections and ordinates for five hundred spirals are added.

THE ALAMO CITY GUIDE. SAN ANTONIO, TEXAS. *Being an Historical Sketch of the Ancient City of the Alamo, and Business Review; with Notes of Present Advantages, together with a Complete Guide to all the Prominent Points of Interest about the City, and a Compilation of Facts of Value to Visitors and Residents.* By STEPHEN GOULD. San Antonio, Texas. 8vo, 151 pages. Illustrated.

Besides such matter as is appropriate to a guide, the author has, in his twenty closely printed chapters, presented to the reader a great deal of historical and statistical information of a more permanent character and more general interest. The history of San Antonio is the history of Texas; for in forty-six days after the massacre of the Alamo, the battle of San Jacinto was fought, the declaration of independence was passed, Santa Anna was captured, and Texas was a nation. The growth of American towns in the West and Southwest to which we have become so accustomed comes out in sharp relief on pages which confront each other in this little book, where, on the one hand, we see, in 1857, the long trains of Mexican carts and "prairie schooners" passing through the narrow streets, by the old adobe buildings; and on the other, read that the total sales of 1881 exceeded twenty-five million dollars. We mention, besides the introductory chapter, giving the General History, the chapters on San Antonio as a Trade Center; Railroads; San Antonio as a Health Resort; Water Power and Manufactures; Building Material; Mines in Western Texas; and Agriculture and Fruit-Growing. Among the illustrations, is one in which the half-Moorish, half-Christian Missions near this new-old town are effectively grouped—Spain, antiquity, and ruin looking down upon a greater than Spain, young, and teeming with energy.

ON A NEWLY-DISCOVERED VARIATION IN THE EFFECT OF PROLONGED STRESS ON IRON.*

By Robert H. Thurston, Stevens Institute, Hoboken, N. J.

Early in the year 1874, the writer presented to the American Society of Civil Engineers a paper on the Strength, etc., of Materials, as Exhibited by a Testing-Machine having an Autographic Registry, in which paper some singular and important effects of prolonged and intermitted stress were described for the first time. In considering the effect of time of application of stress, it was shown that a peculiar difference of effect was observeable in metals accordingly as they belonged to the viscous or non-viscous classes, or, as the writer then stated it, to the iron or the tin class. It was shown that soft metals are subject to a flow which causes gradual yielding under their maximum loads, while common iron and steel, on the contrary, exhibit a singular elevation of the normal limit of elasticity when subjected to internal stress. It was further remarked, that the well-known experiment of Vicat,† in which he found that iron wire loaded with two thirds its breaking weight, as determined by ordinary test, gradually yielded and finally broke, after two years under stress, were indications of the probability that this process of stiffening under load may, nevertheless, be accompanied by a flaw causing ultimate fracture, if the load be heavy. No evidence of such flaw had, however, been detected by the writer in ordinary iron, although occurring almost invariably with other metals. It was finally concluded to repeat the experiment of Vicat in as nearly as possible the same way as the original tests were made.

Two samples of wires made by the Trenton Wire-Works were furnished the writer by Mr. William Hewitt, the vice-president. Both were No. 36 wire (B. W. G.), 0·004 inch (0·1016 mm.) in diameter, and of the same kind of iron. One coil was hard-drawn, directly from the rolls, and the other was very thoroughly annealed, and consequently soft. Lengths of each kind of wire were carefully tested in the usual manner, to determine their strength under ordinary conditions of test, and similar lengths were then measured off for test by prolonged stress. These latter specimens were suspended from a set of coiled springs hung from the ceiling in the study of the writer, where they would be constantly under his eye and where, also, they would be safe against accidental injury. These springs were used because it was found that the jar due to the breaking of one wire was liable to injure those hanging near it. After the wires were suspended, they were carefully loaded and were finally thoroughly painted with oil-paint and left carrying weights as below. The table gives the weights in percentage of maximum loads under test, in the testing-machine, in the usual way :

EFFECT OF PROLONGED STRESS—SWEDISH IRON WIRE.

PER CENT MAX. STATIC LOAD.	TIME UNDER STRESS.	
	Hard wire (unannealed).	Soft (annealed).
95	80 days.	3 minutes.
90	35 days.	5 minutes.
85	18 months, still unbroken.	1 day.
80	3 months.	9 months.
75		17 days.
70		15 months.
65	Unbroken.	15 months.
60		Unbroken.
55		"

These figures seem to reveal an important difference—previously undiscovered, so far as the writer is aware—between hard and annealed iron wire. Hard wire, unannealed and just as it left the draw-plate, sustained 85 per cent its original breaking load, as determined by usual tests, seventeen months; and a wire loaded with 5 per cent less weight, three months (the difference is probably due to some concealed defect in the latter); while the same wire, annealed and then softened so much as to have lost about half as great a maximum load, broke under but 65 per per cent of that reduced load at the end of fifteen months. Those wires which are still unbroken will be left suspended, and, meantime, another series will be put under test. The final result will be reported to the Society in due time, should they all finally break. The broken wires exhibit no traces of corrosion or injury, and the coat of paint with which they are covered is apparently as sound as when first applied. These results evidently more than corroborate the experiments of Vicat, showing progressive disruption in both qualities of wire when heavily loaded. They also exhibit an unsuspected difference in the degree to which this occurs with hard and soft iron, showing the former to be, apparently, the safer. It is interesting to observe that the factor of safety for soft iron, under prolonged stress, must be as great as that for timber under the same conditions, both remaining uninjured by oxidation. These new facts have seemed to the writer so important that he has already announced the conclusion here given by publication in *Science*. They are presented here also as being of especial importance to the engineer.

* A paper read at the Cleveland Meeting of the American Society of Mechanical Engineers.

DRY AND WET SILVER ASSAYS AT THE ENGLISH MINT.

Prof. W. Chandler Roberts, in the thirteenth annual report of the Deputy Master of the British Mint, makes the following interesting statement in regard to the accuracy of the wet and dry methods of making silver assays: Since 1871, the volumetrical method devised by Gay-Lussac has been used for verifying the composition of bars and coin. It only claims to be a means of verifying the standard of an alloy, and consequently it can not be applied to alloys the composition of which is not approximately known. It is true that this objection does not apply to the ordinary practice of the mint, as "trade assay reports" are furnished either with the ingots or with so little delay that no inconvenience need ensue. The reasons which led to the adoption of the "wet" or verification method in France formed the subject of an elaborate series of papers communicated by M. Thiers to the British government in 1836. I have so frequently alluded to its advantages that it may be well to explain why the assay by cupellation was retained in reorganizing the Assay Department.

The commissioners appointed in France in 1829, to investigate the methods of assay then in use, sent alloys of silver and copper, the standards of which were accurately known, to the assayers of the principal European mints, including the mint in this country. The reports of all these assayers indicated the presence of less silver than the alloys actually contained, the deficiencies varying from 0·2 to 1·0 per cent. The evidence gathered by the commissioners led them to recommend the adoption of Gay-Lussac's method, and the authority of the commission, of which the well-known chemists Thénard, Dulong, and Gay-Lussac were members, discredited the "dry" process on the continent, and led to its being employed only for obtaining an aproximate assay. In this country, on the other hand, the method was retained, carefully devised furnaces and appliances were adopted, and the results of the assays were controlled by an elaborate system of "check assays" on standards of known composition. It is unquestionable that the process has been conducted for centuries in this country with great skill by successive assayers of the mint, and, in later years at least, has yielded results which are not merely trustworthy, but deserve the highest confidence.

I was anxious that this process, which may be considered to be historical, should be retained for its own sake, quite apart from the necessity of employing it whenever the composition of the alloy is not approximately known. The traditional skill in conducting the dry process has, I am satisfied, been well sustained, and all the ingots imported for coinage during the past year have been assayed by its means. Since the close of the year, however, 1097 verification assays of ingots have been conducted by the wet process, and in future either process will be used, as special circumstances may require.

THE SUEZ CANAL TRAFFIC.—The statement below shows that the troubles in Egypt, whatever harm they may have done in other quarters, have not resulted in loss to the Suez Canal Company. During the year 1882, 3198 vessels, of a total of 7,122,125 tons gross, passed through the canal. The total movement of navigation and receipts for each year since the opening was as follows :

Years.	Vessels.	Gross Tons.	Receipts. Francs.
1870	486	435,911	5,159,327
1871	765	761,467	8,893,732
1872	1,082	1,439,169	16,407,591
1873	1,173	2,085,072	22,897,319
1874	1,204	2,423,672	24,859,383
1875	1,494	2,940,708	28,886,302
1876	1,457	3,072,107	29,974,998
1877	1,663	3,418,949	32,774,344
1878	1,593	3,291,535	31,098,220
1879	1,477	3,236,942	29,686,060
1880	2,026	4,344,519	39,840,487
1881	2,727	5,794,401	51,274,352
1882	3,198	7,122,125	60,545,881

Compared with 1881, last year shows an increase of 17·27 per cent in the number of vessels, 22·91 per cent in the tonnage, and 18·08 per cent in the receipts. The average tonnage per ship was 2227 tons. During the year, 407 vessels passed through the canal for the first time. The 3198 vessels which made the passage consisted of 1610 from the Mediterranean to the Red Sea, and 1588 from the Red Sea to the Mediterranean. The total number was made up of 2361 trading steamers, 501 mail steamers, 134 vessels chartered by the British government, 154 government vessels, 10 yachts, one floating dock, and 37 tugs. The passengers carried consisted of 62,898 soldiers, 38,288 civilians, 6390 pilgrims, 797 convicts, and 18,499 emigrants.

THE DIAMOND-FIELDS OF SOUTH AFRICA.

At the meeting of the British Institution of Civil Engineers, the paper read was on the Diamond-Fields and Mines of South Africa, by Mr. James N. Paxman, Assoc. M. Inst. C.E.

Kimberley, the center of the most important field, is situated in Griqualand West, above 700 miles northeast from Table Bay, and 450 miles inland from Port Elizabeth and Natal on the east coast. Lines of railroad are in course of construction from Table Bay and Port Elizabeth to Kimberley, and are about half completed. In Griqualand, there are several diamond mines, the principal of which are Kimberley, De Beer's, Du Toit's Pan, and Bultfontein. In the Orange Free States, there are also two mines, namely, Jagersfontein and Koffeyfontein, the first of which produces fine white stones. The mines are all divided into claims, the greatest number of which are to be found in the Du Toit's Pan mine. Bultfontein comes next.

The deepest and most regularly worked is the Kimberley mine. The next deepest is De Beer's, which, however, is very unevenly worked. Then follow Du Toit's Pan and Bultfontein. The Du Toit's Pan mine ranks next in importance to the Kimberley mine. Diamonds were first discovered in 1867 by Mr. O'Reilly, a trader and hunter, who visited a colonist named Van Niekirk, residing in Griqua. The first diamond, on being sent to the authorities, was valued at £500. Considerable excitement was caused throughout the colony, and the natives commenced to look for diamonds, and many were found, among which was one of 83½ carats, valued at £15,000. In 1868, many enterprising colonists made their way up the Vaal River, and were successful in finding a good number of diamonds. The center of the river diggings on the Transvaal side is Klipdrift, and on the opposite side Pniel. In all there are fourteen river diggings. Du Toit's Pan and Bultfontein mines were discovered in 1870 at a distance of twenty-four miles from the river diggings. The diggers took possession of these places. Licenses were granted giving the first diggers a right to work. In 1871, De Beer's and Kimberley mines were discovered, and, in 1872, Mr. Spalding's great diamond of 282½ carats was found at the river diggings.

The mines are of irregular shape, and are surrounded by reef. The top reef is a loose shale, and has given great trouble from the frequent slips. Below this are strata of trachytic breccia and augite; the formation is then seamy to an unknown depth.

Within the reef, the surface soil is red and of a sandy nature. The next stratum is of a loose yellow gravelly lime, and the third blue, of a hard slaty nature. This last is the real diamantiferous soil. Large stones have been found in the "yellow," but the working of this generally does not pay. Kimberley mine, however, has paid very well all through. The method of working in deep ground is determined by roadways running north and south. The soil is hauled up to these roadways, and taken to the sorting-tables. The roadways decaying shortly after exposure to the atmosphere, a system of hand windlass was adopted, which worked very well for a time until horse-whims were introduced in 1873. The depth of the mines increasing, horse-whims had to give way to steam-engines in 1876.

The first diggers treated on an average ten loads per day each party. At the present time, the least taken out by an engine, when fully employed, is 250 loads per day. The cost of working, with present appliances, the first 100 feet in depth, is 3s. 6d. per load; the second 100 feet (mostly blue), 5s.; the third 100 feet, 8s.; and the fourth 100 feet, 11s. Through scarcity of water, a system of dry-sorting had to be resorted to for several years; but it was superseded by the introduction of washing machinery, which is now generally employed.

At the beginning, through inexperience, many serious mistakes were made. When the first diggers reached the bottom of the red sand, they thought no diamonds would be found in the next stratum. When, however, diamonds were found in the second stratum, the diggers had again to remove the *débris*, and so also when the "blue" was reached. Some of the claims in the Du Toit's Pan and Bultfontein mines are irregular in shape. The other mines, however, have been properly and regularly laid out. One or two shafts have been connected with the mines by underground galleries. These galleries are convenient in the case of falls of reef. Labor, at first, was cheap; but from 20s. per month, wages rose to 30s. per week, and food. The yellow soil offers no difficulty in working, being loose and broken, but the blue soil requires blasting.

Several methods were adopted for extracting the soil and carrying it from the mine before steam was introduced. The cost of wood for heating purposes was a serious item; but good coal has now been found at 160 miles from Kimberley, costing £13 per ton. Another serious item of expense is the transport over natural roads only, costing from £18 to £30 per ton.

Water is dear, and water-heaters are fitted to each engine, by which 33 per cent of the water is again used, thus saving one third. The boilers are of the locomotive type, mostly of steel, to save weight, and thus reduce the cost of transit. The fire-boxes are also made of steel of very soft and ductile quality. A semi-portable engine is made for driving the wash-mill. The engine is so arranged that it may be removed from the boiler and placed separately. The boiler is made to work at a pressure of 140 pounds per square inch. Automatic cut-off gear is fixed to each engine, and the governors are provided with a spiral spring for adjusting the speed. A screen, or cylinder wash-mill and elevator, is used for dealing with the diamantiferous soil. Standing wires are fixed at the back of the machinery, and pass over a frame fixed at the top of the mine, the ends of the wires being secured to strong wooden posts. After the blue soil has been blasted and collected into trucks, it is placed in tubs, which ascend the standing wires. It is then emptied into the depositing-box. The yellow soil may be put into the wash-mill directly, also that portion of the blue which has passed through the screen fixed over the depositing-box. The remainder of the blue, which is spread out to a thickness of four inches or six inches on the depositing ground some distance from the mine to dry, is delivered into the upper part of the screen. The return water from the elevator, with a portion of fresh water, is also discharged at this point, and operations are thus greatly facilitated, the soil becoming thoroughly saturated and passing more easily down the chutes. The large pieces which will not drop through the meshes of the screen are discharged into trucks at the lower end and carried away. The smaller pieces with water, in the form of sludge, fall through into a chute, and thence are conveyed into the wash-mill pan, and there kept in constant rotating motion by agitators. The diamonds and other pieces of high specific gravity sink to the deepest part of the pan, and the remainder of the sludge is forced over the inner ledge to the elevator. The sludge is then lifted and thrown upon an inclined screen and down the chute over the side of the bank. The residue left in the pan at the end of the day's work is passed through a pulsator, in which, by the force of water, the mud and lighter particles are carried away, leaving behind the diamonds, agates, garnets, and other heavy stones. It is the practice occasionally to put a few inferior stones in the soil, to test the efficiency of the machinery.

In 1881, the author paid a visit to Kimberley, and found the industry a large one. The post-office showed the value of diamonds passed through the office in one year to be £3,685,000. Illicit diamond traffic has hitherto been a source of great trouble at the fields. It is a question whether this industry will ever cease; in any case, there is no doubt but that it will last for over a century. It is believed that the main bed of diamonds has not yet been reached, and that the mines in operation are merely shafts leading to it. Now that the water-works are finished, with a bountiful supply of water, coupled with the great boon of railroads to the fields, and the advantage of a law recently passed for the prevention of illicit buying, a great and prosperous future is in store for the diamond-fields.

RECENT RESULTS OF THE JAMESON COKING PROCESS.

Mr. T. B. Lightfoot, C.E., in a paper read before the Society of Arts, gives the following as the results obtained with the Jameson method of utilizing the by-products in the manufacture of coke:

Kind of coal.	Gals. of crude oil.	Ammonia estimated in pounds of sulphate.
Shiremoor	13·00	9·87
Brancepeth cannel	12·20	6·00
Longhirst, small	9·28	17·78

The following may be taken as an average analysis of the crude oil:

	Per cent.
Lubricating oil	39·5
Burning oil	37·7
Paraffine scale	13·5
Tar and loss	9·3
	100·0

The composition of the gas collected from the Jameson ovens, after its passage through the condenser, varies according to the coal under treatment and the length of time the charge has been burning. An approximate average is given in the following table:

Carbonic acid	3·5
Carbonic oxide	27·5
Hydrogen	29·3
Oxygen	1·1
Nitrogen	38 6
	100·0

THE ELWELL-PARKER ACCUMULATOR.

A new accumulator has been recently brought out in England by Messrs. Elwell & Parker. The *Engineer* describes the method of making it as follows: Strips of sheet-lead nine inches wide and any convenient length, weighing two pounds to the square foot, are passed through a machine which first punches holes entirely through them and then impresses them with indentations, which act as distance-pieces to keep the layers of each plate apart. The holes secure a free circulation to the electrolyte. These strips are then rolled spirally into cylinders containing, in the small cells, three thicknesses of plate each, the joints being made secure by fusing with a soldering-iron, and an anode of much thicker lead being fused on at the same time. Each cell contains eight of these cylinders a quarter of an inch apart. The lead cylinders are first placed in a bath containing a dilute solution of nitric and sulphuric acid, and left there for twenty-four hours. The effect of this bath is to minutely honeycomb the lead plates, putting them into the most favorable condition for "formation" by the electric current. There is also formed upon the surface of the plates a deposit of sulphate of lead, the greater part of which is subsequently reduced to peroxide, part of it being first washed off. The plates, on being taken from the bath, are washed, and then placed in the ordinary dilute sulphuric acid solution in the cell. They are then charged in one direction for six hours with a current of 12 ampères, discharged in about three hours through ten Swan 45 volt, 20-candle lamps—twenty-two cells give 45 volts—and charged again in the reverse direction. They are then ready for use. There is then no sulphate visible, the peroxide plate being a rich, dark brown color, of smooth, hard crystalline appearance, and the negative plate presenting a clean surface of ordinary lead color. The cells are coupled by clamping the electrodes together. The plates or cylinders are retained in position by notched vulcanite frames underneath, and notched distance-pieces of the same material on the top, thus leaving the entire space between the plates and a space underneath them open for the free circulation of the electrolyte. The period occupied for the cutting up of the lead strips to the complete charging of the battery ready to send out is only forty-eight hours. Earthenware cells are generally used; but the company manufacturing under the patent also uses wood cells, coated inside with a composition of gutta-percha; these are preferable where strength and lightness are required. The quantity these cells will give out at an electro-motive force of two volts or rather more—same as the original Planté cell—is about forty ampère hours when sent from the works; that is, supposing an accumulator is required to give a current at an electro-motive force of 45 volts, twenty-two of these cells will give a current of 10 ampères for four hours before any of the cells "give out." But the capacity of the cell may be greatly increased by occasionally reversing the charging currents, as in the original Planté cell. The cells are packed in small cases of three cells, carpet being slipped between the plates. They seem to travel safely thus.

UTILIZING BURNING CULM-PILES.

An interesting application of a patent analogous to those for utilizing the waste products of coke, recently taken out by Mr. H. L. Armour, and the property of the Jameson Coke Company, Limited, has just been made in the case of a pit-heap at Seaton Burn Colliery, in Northumberland. A pit-heap is a deposit for quantities of small coal and dust, for which, as a rule, no market can be found, as well as for shale and iron pyrites met with in working the coal. These heaps are generally burning, and in very many instances, give off so much smoke and dirt as to become a terrible nuisance to the neighborhood. This was the case at Seaton Burn; but by simply covering the heap with sand, and sinking a number of iron pipes connected with a main, in which a constant suction is maintained, all offense has been removed, and a stream of gas, yielding both oil and ammonia, is obtained. In this manner, a worse than valueless property has been converted into a profitable one, and, as the system is now in course of extension to large heaps at Kelvinside, near Glasgow, it is to be hoped that before long an end will be put to one of the greatest nuisances in colliery districts.

FURNACE, MILL, AND FACTORY.

The Iowa Barbed Iron-Works will be removed from Johnstown to Easton, Pa. The mills are running fourteen hours a day with heavy orders.

A large iron furnace is among the possibilities at Tyrone, Pa.

The Ohio Multiplex Boring Machine Company has been incorporated at Cleveland, Ohio, with a capital of $150,000.

The Pennsylvania & New York Railroad Company is building a new foundry at Sayre, N. Y. The main building is to be 124 by 63 feet, and over three hundred men will be employed.

The Deane Steam-Pump Company, of Holyoke, Mass., has removed its office and warerooms in Philadelphia from No. 43 South Fourth street, to No. 49 North Seventh street.

The Cummer Engine Company, of Cleveland, Ohio, will send one of its 150 horse-power automatic engines to the Louisville Exposition.

Calamining is the name of the new process for coating iron, introduced by Messrs. Everson, Macrum & Co., of the Pennsylvania Iron-Works, Pittsburg, who find it a very successful substitute for galvanizing.

The long-unused property of the New York Steam-Engine Company, at Worcester, Mass., with buildings, engines, etc., has been purchased by William Allen & Sons, of the Worcester Boiler-Works, and is to be fitted up for their occupancy.

The Keystone Iron-Works, of Reading, Pa., J. V. Craig & Son, proprietors, resumed work June 18th, after six months' idleness.

The Union Iron-Works, San Francisco, intend to erect extensive works during the summer, and will connect them with the railroad.

A firm in Lansingburg, New York, has nearly finished a "paper steamboat," for a Pittsburg company. The vessel is 20 feet long, can seat twenty-five persons, and will carry three tons. Its sheathing is a solid body of paper three-eighths of an inch thick. A bullet from a revolver, fired at the sheathing from a distance of only four feet, neither penetrated nor abraded it.

A telegram from Pittsburg to the daily newspapers says that Oliver Brothers and Phillips's lower mills, and several other mills at Pittsburg, will close July 1st for repairs. The stoppage will consume from four to six weeks, and is as welcome to the workmen as to the operators.

The Northeastern Steel-Works Company, Middlesborough, England, formed some twelve months ago, has practically begun operations, making its first experimental blow in one of its converters on Thursday, May 31st. They have four fifteen-ton converters. Messrs. Thomas & Gilchrist, the well-known inventors of the basic system of dephosphorizing ores, are members of this firm, which includes many of the leading metallurgists in Cleveland. The works are specifically designed for the manufacture of steel from Cleveland ore. The phosphorus contained in the iron of the first charge of the converter was between 3 and 4 per cent, and careful analyses of the newly-blown steel resulted in the discovery of only ·02 per cent, which is about one fourth of the quantity usually contained in steel made from the purest hematites. The machinery in the works is laid out with the view to making rails and billets, as well as slabs, etc., for plates of all descriptions and qualities. The probable output of the works, when in full operation, will be from two to three thousand tons per week.

A terrific explosion occurred on the morning of June 22d at blast-furnace No. 5 in the North Chicago Rolling-Mills. Thirty-five tons of molten iron were scattered in every direction. Two men were horribly burned, and will die. Sixteen men were more or less severely burned, but none, it is believed, seriously.

No. 2 furnace of the Thomas Iron Company, at Hokendauqua, has been blown out and will undergo thorough repairs. Five furnaces are now in blast at Hokendauqua. All of the seven blast-furnaces of the Bethlehem Iron Company, except No. 2, are in full blast, and are worked to their fullest capacity. No. 2, which was blown out for repairs several weeks ago, will, it is thought, be lighted in a few days. One thousand men have struck at the Bethlehem works.

The Lincoln Iron-Works, Lincoln, Mass., manufacturers of stone-mill and quarry machinery, are driven day and night to fill orders, mainly on gang-saws for the marble-producing mills. Orders are nearly filled for thirty gangs of these saws. The company also manufactures a heavy line of wood-working machinery, shafting, pulleys, and gearing. A large business is also done in rubbing-beds for marble mills, which is one of its principal specialties.

Twenty-five of the thirty-five blast-furnaces in the Mahoning and Shenango valleys, Ohio, are in operation, producing 2000 tons of metal per day.

A break last week at the bottom of Leesport Furnace, beneath the trough, caused the escape of about thirty tons of iron, which ran into the casting-house, and at one time threatened the destruction of the building by fire. Prompt action of the men, however, prevented any further damage.

During their usual shut-down this summer, the William Anson Wood mower and reaper works, at Youngstown, Ohio, contemplate enlarging their foundry, in order to increase their capacity for production.

The Missouri Malleable Iron Company, which recently increased its capital stock, is making arrangements to more than double its present capacity by building one or two more furnaces, putting in new machinery, and extending its foundry by putting up a new addition. These improvements will be completed some time in July, when the company expects to be able to meet promptly every order for malleables. Its foundry department is full of work.

Swede Furnace, near Bridgeport, Montgomery County, Pa., is to be put in blast again at an early day.

Citico Furnace, Chattanooga, Tenn., is about half finished. The chimney, which is completed, is 170 feet high. The furnace shell will be completed in a few days, and will be 69 feet high and 22 feet in diameter at the bosh. No less than 100 men are working at furnace.

The Laclede Fire-Brick Manufacturing Company is now operating 23 kilns, 5 of which are 24-foot ones. The retort department is crowded beyond precedent, the orders for this kind of goods exceeding by more than one hundred per cent those of any other season. Among the recent orders were one from the Springfield (Ohio) Gas-Works for the building of five benches of sixes, being the second order from that works; one from the Wheeling Gas-Works for the building of twelve benches; and another from the Cincinnati Gas-Works for 600,000 fire-brick.

At the Atlas Works, Pittsburg, the first plunger for No. 1 engine at the Negley's Run pumping-works has been cast. Last week, the furnace was charged with 14 tons of metal, but the plunger, when finished, will only weigh eight tons. The Atlas Works have the contract to replace all the defective castings in Nos. 1 and 2 pumps, embracing four plungers, four pump-barrels, four sections of valve-chambers, and two check-valves. When completed, the castings will have an aggregate weight of 275 tons.

MINERAL PATENTS GRANTED BY THE UNITED STATES LAND-OFFICE.

The following patents were issued under date of June 15th, 1883:

ARIZONA.

TUCSON DISTRICT.

Theodore F. White *et al.*, Silver Cable lode.

CALIFORNIA.

THE BODIE DISTRICT.

Nathan Rhine, Hirsh gold and silver mine.

HUMBOLDT DISTRICT.

Samuel Ambrose *et al.*, placer.

SAN FRANCISCO DISTRICT.

Samuel Baker, coal.

STOCKTON DISTRICT.

Heirs of A. M. Mitchell, deceased, Bonny placer mine. John Batten *et al.*, Bowling Green placer.

COLORADO.

CENTRAL CITY DISTRICT.

Theresa Jaeger, Little Emily lode. George W. Hall, Colorado Extension lode Edmund R. Marsh, O. and M. lode and mill-site. Alexander McLeod, Notaway lode. George A Reuter, Iron lode. J. P. Ward, Stella lode. Hal Sayr, Autocrat and Esperanza lodes. Francis G. Nagle, Gregory lode. Marshel Silverthorn, placer and Willow Creek placer. Julien Fountain, Independence lode.

DEL NORTE DISTRICT.

John R. Burrows *et al.*, Baker lode. William P. Linn, Rawley lode.

DURANGO DISTRICT.

IXL Tunnel Company, Tom Paine lode. Peter Fassbinder, Neptune lode American Midland Mining and Milling Company, Caribbean lode.

LAKE CITY DISTRICT.

Bessie Bascom Consolidated Mining Company, Little Rock and Little Chief lodes. Philip N. Nichols, Rob Roy lode. Oneida & Belcher Consolidated Mining Company, Belcher lode. Hugh J. Alexander, Dictator lode. C. E. Schoellkopf, Revenue lode. M. M. Engleman *et al.*, Lulu Carroll lode. John S. Hough *et al.*, Lilly Lode. Hennan Beckurts *et al.*, Uncle Sam lode. William E. Webb *et al.*, Benjamin Franklin lode.

LEADVILLE DISTRICT.

Roseville-Alta Consolidated Mining Company, Garfield and Roseville lodes. Toronto & New York Consolidated Silver Mining Company, Toronto lode. William J. Lynd, Valverde lode. William Lefman, Ohio Wave lode. Clifton Consolidated Mining Company, Edwin Forrest lode. Henry Frankle *et al.*, Laura Levy lode. G. T. McDonald *et al.*, Jay Gould lode. J. O. Hudnutt *et al.*, Whale and Ned lodes. Lennox Mining and Milling Company, May Day lode. T. J. Oliver *et al.*, Little Dick lode. Thomas R. Frazer, Chance lode. Franklin K. L. Bush, Commodore placer. Americus L. Pogue, Independence placer.

PUEBLO DISTRICT.

Bunker Hill Consolidated Mining Company of Colorado, Concord lode. Tellurium Milling and Milling Company, Poor Man lode. Edward Chambers, coal.

IDAHO.

BOISE CITY DISTRICT.

W. S. McCormick *et al.*, Point Lookout lode.

MONTANA.

HELENA DISTRICT.

Lewis Stettheimer *et al.*, Garfield and Silver Crown lode. Charles Schlesinger, Exile of Erin lode. Samuel Neel *et al.*, Pilot lode. Orlando B. Barber *et al.*, placer. Montana Copper Company, Hattie Harvey and Bully Boy lodes. Robert C. Walker *et al.*, placer.

NEVADA.

CARSON CITY DISTRICT.

Ferdinand S. Van Zandt, Lloyd lode.

UTAH.

SALT LAKE CITY DISTRICT.

Samuel Kahn *et al.*, Murphy lode. Phœnix Mining Company, Stanley lode. Carl R. Briggs, coal.

GENERAL MINING NEWS.

ARIZONA.

PECK DISTRICT.

BLACK WARRIOR.—Dispatches from the general manager state that the newly-purchased mill of this company has been started and is making a highly successful run. Two bars of bullion were shipped on the 26th inst.

CALIFORNIA.

MONOCOUNTY—BODIE DISTRICT.

BODIE CONSOLIDATED.—The official report for the week ended June 16th shows: Ore crushed, 165·6 tons; average assay value of pulp, $33.33 per ton; of tailings, $4.50. West cross-cut, 1000 level, in 26 feet. North drift, same level, in 238 feet. North drift, 800 level, is 591 feet long. South drift from winze No. 6 at the 640 level is 181 feet long. Uprise No. 23 is up 33 feet. Winze No. 5, from the 780 level, is 53 feet deep.

STANDARD CONSOLIDATED.—The superintendent writes to the vice-president, under date of June 12th, as follows: Your letter of the 31st ultimo to William Willis, secretary, is at hand. The increase in our bullion shipments is on account of an improvement in the north stopes on the 500-foot level, and the discovery of some fair milling ore on the 1000-foot level. The south drift No. 2, 1000-foot level, which has been driven from the main east cross-cut a distance of 102 feet, shows the vein from five to seven feet wide. We are stoping from this drift, and although the ore is as yet rather low-grade, this is the most important development made below the 500-foot level, and it gives every indication of making an important ore-body. North drift No. 1, 1000-foot level, 400 feet east of the shaft, is in 164 feet, showing two feet of milling ore. The 1200-foot east cross-cut is in 287 feet, and is pushed ahead as fast as possible. There is no other change to report throughout the mine.

PLUMAS COUNTY—GREENVILLE DISTRICT.

CRESCENT.—On the return of Mr. Davis, work was resumed at the mine and mill.

GREEN MOUNTAIN.—The new mill is running steadily as usual. Some very good ore has lately been taken out in the upper levels, the yield of bullion showing a gratifying increase. In the tunnel, the ledge has improved very much in appearance during the past few days.

Digitized by Google

CANADA.

It may be well, says a correspondent of the Montreal *Gazette*, to remind persons interested in mining in Manitoba and the Northwest territories, for the precious metals and for minerals other than coal, that the regulations in that behalf recently published by the Department of the Interior are not actually in operation, nor is it intended that they shall come into operation at present. It is the purpose of the department, we understand, to place these regulations before the public for some time, so that opportunity may be given for their full discussion and a chance for having them amended if shown to be necessary. It is safe to say that representations on the subject from any quarter would, if submitted to the department in the regular way, receive the most careful and respectful consideration.

MANITOBA.

ARGYLE.—The mine is worked steadily. The recent clean-up gave a return of some $25 per ton, with a good deal left in the tailings. Two Frue vanners are now going up to save these tailings.

PINE PORTAGE.—The mill has started up. The ore is said to be refractory, but will concentrate well and give good returns over cost of treatment.

WINNIPEG CONSOLIDATED.—Over eighty feet of drifts have been opened up, which show a body of high-grade ore. The small mill has not been running of late, as the superintendent found he was losing about 60 per cent, and all the work had to be done over again. They have ordered new grinding and amalgamating pans, which are manufactured at Winnipeg with exemplary slowness. With these in, it is expected that 85 or 90 per cent of the value of the ore wil be saved.

NEWFOUNDLAND.

The three most active copper mines are, as reported, the Tilt Cove, Bett's Cove, and Little Bay. Statistics for last year have not yet been received. The first of these mines opened was that of Tilt Cove, and up to the close of 1879, returns showed that the quantity of copper ore exported from this mine was nearly 50,000 tons, valued at $1,572,154. The value of the nickel ore exported from the same mine, at that date, was $32,740. From 1875 to 1879, the quantity of ore exported from Bett's Cove mine was 123,556, valued at $2,982,836. Little Bay mine was opened in August, 1878. At the close of that year, seven cargoes of ore had been shipped, amounting to 10,000 tons. In 1879, 19,2721 tons were sent to England. In 1880, the exportation reached 16,610 tons; and in 1881, 20,640 tons of ore. Last year's returns are not yet at hand; but it is understood that Little Bay mine increases in productiveness, and that the quantity of the ore improves the deeper the workings have gone.

QUEBEC.

Judge Caron, in the Superior Court, June 22d, gave judgment in the long-pending case of the Queen *vs.* the Delery Gold Mining Company, in favor of the defendant. This case was brought relative to the patent right of the company. The result of this judgment will doubtless cause a boom among the Beauce gold miners, and induce them to extend their operations.

COLORADO.

CLEAR CREEK COUNTY.

CASHIER.—Messrs. Maccie & Co. are working about 200 feet in from the entrance of the fourth adit on this well-known Sherman Mountain mine, on forty-six inches of mineral, which gave a mill-run from sixty-five sacks last week as follows: Total weight, 3723 pounds; running, first-class, 301 ounces per ton; second class, 152 ounces. Net receipts for the lot, after deducting mill charges, $452.31. Several parties of lessees are working in different parts of the mine.

DUMONT.—The lessees have struck six feet of good milling ore and twenty inches of solid smelting ore in the lower level on the Albro mine. This level starts in on the vein where it crosses the gulch, and is the deepest working on the whole lode. The Lee lode is worked by a shaft which is 86 feet deep, and shows a continuous streak of ore 16 inches thick. The Lincoln cross-cut tunnel, near town, has at last struck the California lode at a distance of 600 feet, having been obliged to run nearly 100 feet farther than was originally expected.

CUSTER COUNTY.

BULL-DOMINGO CONSOLIDATED.—This company has reorganized, and is hereafter to be known as the Bull-Domingo Mining Company. It has a capital stock of $200,000, divided into 200,000 shares of $1 each, unassessable.

DOLORES COUNTY.

SOUTH PARK.—This mine was located in 1879 by Houton, Costello, and Pulver, and was bonded some months ago by Colonel C. A. Jockmus and Hon. E. Pisko, of Denver, and W. J. Cox, of Rico. About 200 feet of tunnel had been run at the time the property was bonded. At the end of a 300-foot tunnel, ore was found in small quantities, and by further exploration the quantity increased rapidly. Top, bottom, and sides of several drifts, radiating from a common point at the extremity, disclose one deposit of manganese ore which mill-runs 334 ounces in silver per ton. Day and night shifts are now at work. A large ore-house is building at the entrance to the tunnel, and a wagon-road is under construction, to be completed in four days. The distance from Rico to this mine is about a half-mile, and the same distance from the mine to the Grand View smelter, where the ore is now shipped. Blasting is not even necessary, as the ore is so soft.

PUZZLE EXTENSION.—This mine has been producing ore in considerable quantities for a long time, and the Santa Clara mill has been treating it constantly. The mine is owned largely by the stockholders of the Santa Clara mill, who have profited largely by the purchase.

FREMONT COUNTY.

CANON CITY OIL COMPANY.—This company has located its well on Mr. Stump's farm, on Oil Creek, four miles northeasterly from town. This is the third working company now operating in this oil basin.

COAL, OIL, AND INVESTMENT COMPANY.—At about 200 feet below the first oil, and at a depth of 1435 feet, this company struck another vein of oil that is of lighter specific gravity, and which seems to be present in good quantities. It will now stop boring and put in the pumping machinery.

LAKE COUNTY.

Late Leadville exchanges contain the following:

The *Herald*, in its description of Colorado Gulch and Little Frying Pan Mining districts, located six miles west of Leadville, says that this section embraces the Sugar Loaf and surrounding mountains, forming a portion of the group of foot-hills situated at the base of Mount Massive. The districts show but one species of rock, and that is a coarse-grained granite, the Archæan rock underlying the Leadville sedimentary formations. As a consequence, an entirely different vein system from that to the east of Leadville is found in this district, and instead of nearly horizontal contact-veins, the country discloses veins which to all appearance are true fissures. The veins show few characteristics not met with in any mineral country under similar physical conditions. The greater number of the leads have a course nearly north and south, being parallel with the axis of the main range of mountains, and their dip is quite uniformly to the westward. The width of the veins varies, extending from two to twelve feet; sometimes presenting well-defined walls, and again the vein-matter and country-rock is imperceptibly blended, so that a trained eye can scarcely distinguish any line of demarkation. The vein-stone is a fine-looking quartz and decomposed gouge matter, carrying the base and precious metals as sulphides. Occasionally native silver is also disclosed, but this feature is rather the exception than the rule. The base minerals associated with the ores are iron, copper, lead, and zinc, usually as sulphides. The most prominent mines of the Colorado Gulch and Little Frying Pan districts are the following: Dinero, Gunnison, Consolidated Virginia, Laplander, Birdie R., Shields, Venture, and Welsh, having in the aggreate an estimated output of twenty or thirty tons a day, when all are working under favorable conditions. At present, considerable difficulty and delay are occasioned by surface water, which will be obviated in a short time when the sides of the mountains have been cleared of their winter's accumulation of snow. At present, while water is plenty, the product of the melting snows, the Frying Pan placer is actively and successfully worked. The gulching season here never exceeds two months, and during many years there is scarcely sufficient water for four or five weeks' work. This year, Mr. William Emery, the owner of the placer, begun work June 4th, since which time he has washed out quite a pit of fairly good pay-dirt, and is now preparing to make a clean-up. Last year, work was done equal to one hundred days, and the final clean-up yielded, for the season, $675. The results for this year are expected to be about the same. The ten-stamp chloridizing and amalgamating mill of the Shields Mining and Milling Company, located at the junction of Colorado and Little Frying Pan gulches, has been closed down since April 20th, but will start up again next week, having been assured ample ore from the large producers of the section.

AMIE.—The company in January, 1881, adopted a system of leasing out portions of its mining ground, which has since been pursued. In December, 1882, a fine ore-body was discovered from the No. 3 shaft workings, which in a few months yielded about $130,000, the company getting about 30 per cent royalty therefrom. There are now five leases on the property, from all of which the company is deriving a small royalty. The company is also itself working the No. 3 shaft. The workings of the northern part of the mine are said to be looking well and improving. In this portion of the mine, there yet remains a large territory of unexplored ground.

CLIMAX.—Little work has been done by this company during the past two years, and owing to the increase of its debt it was recently proposed to dissolve the company and settle up its affairs. All the property is now under lease, and work is done under five leases. Of these only one—covering No. 1 shaft—is now paying. It is stated that the company has, from royalties received, been able to pay its indebtedness, and now has a fair prospect of success. The Climax mine proper has but small territory, the claim for the greater part of its length being but forty feet wide. The claim widens toward the north and in the portion which is now showing the best. Much confusion has been occasioned regarding the Climax by the fact that the original Climax claim conflicted with other locations, the "Climax Contract," the "Montana," and the "Deer Lodge," embracing a portion of the original full claim as located. The Climax Contract and Montana have recently produced largely, and hence the impression has spread that the Climax itself had been producing a large quantity of ore. It is reported that there are strong indications that the north ore-chute of Fryer Hill, which yielded so largely in the Montana, also extends across the Climax. The lessees of the No. 1 shaft are making substantial improvements. Their drifts north extend into entirely unexplored ground. The Climax is under the same management as the Amie, and expenses are said to be kept very low.

COMIQUE.—In this mine, situated on the north side of Fryer Hill, and abandoned for several years past, a body of iron ore has been opened.

IRON SILVER.—The following statement shows the condition of this company June 16th:

Balance May 1st, 1883	$206,445.46
Product for May	127,108.64
	333,554.10
Expenses May month	82,741.19
Balance May 31st, 1883	250,812.91
Net product to June 15th, estimated	22,183.71
	272,996.62
Dividend June 16th, 1883	100,000.00
Balance in bank to date	$172,996.62

LONG & DERRY.—Work has started on this property, which has been idle for a year.

NELLIE S.—A strike of ore containing gold has been made in this mine, situated in Printer-Boy Hill.

TENDERFOOT.—This mine has been leased to Messrs. Slater & Leonard.

LARIMER COUNTY.

CARBONATE.—Work will soon be commenced. The tunnel is in 600 feet.

NORTH PARK & VANDALIA MINING AND SMELTING COMPANY.—This company will probably put up reduction-works this summer. It owns the Endomile, and has a large amount of ore on the dump.

RARUS & MAUD S. MINING COMPANY.—The directors of this company, organized some time since, have decided to push developments on their properties at once. They are now working a force of men, and the mines show up a fine body of mineral, which improves greatly with the development.

WOLVERINE.—This company has ordered a smelter, which will be put up some time this summer. The superintendent of the mine expects to increase his force of men on this mine soon to 150 men.

PITKIN COUNTY.

MANVILLE SMELTING COMPANY.—The parties who have for some time past been negotiating for the North Texas smelter have secured the same, and have organized a company under the above name. Preparations are making to blow in the smelter at once.

DAKOTA.

Ground has been broken for the railroad to connect the Portland and Trojan groups with the projected new mill on Spearfish, five miles distant. Work will be prosecuted as rapidly as possible.

ESTRELLA DEL NORTE.—The damage made by the recent floods does not amount to more than $1200. No serious delay in operation has been caused.

FAIRVIEW.—An interest in this mine has been disposed of to parties who will at once erect a mill on the property for the reduction of ores. This mine is one of the most extensively developed of the Central Hills.

FATHER DE SMET.—Report of superintendent from June 1st to 8th shows ore extracted from first, second, and third levels 1950 tons. Ore milled, 1950 tons. Golden Gate north header advanced 6 feet. Header in 131 feet. Report from June 7th to 15th shows ore extracted from first, second, and third levels, 2150 tons. Ore milled, 2150 tons. Golden Gate north header advanced 8 feet. Header in 139 feet. All development-work stopped; cause, scarcity of fuse.

GOLDEN SUMMIT.—A force of ten men is now at work at the mine. The main shaft is down 30 feet, and the breast 200 feet in extent. The mill is not in operation, owing to the bad condition of roads and absence of bridges. Every bridge has been washed away from Spring Creek.

GEORGIA.

CALHOUN.—Work is pushed on the flume-line, which is undergoing change to admit of beginning operations at a more favorable point. In consequence of this change of base, the forty-stamp mill is now idle. The new pump has arrived and will soon be in position.

CHICAGO & GEORGIA.—The twenty-stamp mill is now going up.

FINDLEY.—The true reason for the stoppage of work at this mine is said to be a reluctance on the part of a portion of the stockholders to bear their pro rata of the expense of doing certain dead-work which is considered necessary before the mine can again be made to pay.

GARNET.—Work at the mill will begin shortly.

IVEY.—The sixty-stamp mill is completed, and only awaits the completion of

Digitized by Google

the flume-line and tubing to start up. A force is at work piping the cut, and as soon as this is brought to grade, the new flume will be constructed. The twenty-stamp mill is working on ore from the cut. The ditch is delivering about 200 inches of water, and increasing daily.

SINGLETON.—Work is pushed vigorously in all departments. The new twenty-stamp mill is running on full-time, as is also the old five-stamp mill near by. For some weeks past, a small force has been employed in driving a tunnel from the branch, to tap the vein at the lowest available point, and a few days since a vein, now believed to be the same, was cut. A mill-run of a few tons, just finished, gives very satisfactory results. An average sample from across the vein, including slates as well as the quartz, yielded by assay $3.97 per ton.

MEXICO.

A party of capitalists has examined the copper mines at Nocasari, Sonora. The final arrangements for the purchase of the property have been made, and the price agreed upon is stated to be $350,000. Mr. Lird, of the firm of Motler & Lird, San Francisco, who went with the party, is making estimates for the erection of two thirty-ton smelters at the mine.

A rich placer field is reported 90 miles east of the city of Chihuahua, comprising 3000 acres, with an average depth of 75 feet. The ores run low in silver, high in lead, but are in immense deposits. The property was recently sold to G. M. Shaw, of Socorro, New Mexico, who will work it on a large scale.

ENCINO.—Work at this mine, situated in Pachuca, has been stopped on account of the non-completion of the reduction-works now building by the company. When completed, mining will immediately begin.

SANTA EDUWIGES.—A large invoice of machinery for working this mine, situated in Chihuahua, has reached its destination. This mine is located in the famous Jesus Maria District, and has been worked with profit for over a century. The ore carries both gold and silver and runs three hundred ounces to the ton.

SANTA EULALIE.—The work on the buildings, mill, etc., of this company is progressing with great rapidity.

MICHIGAN.

The Marquette *Mining Journal* gives the following table, which exhibits, in gross tons, the total lake shipments of iron ore from upper peninsula ports the present season, up to and including June 20th, together with the amount shipped from the same ports during the corresponding period of last year:

Name of port.	1882.	1883.
Escanaba	525,748	306,029
Marquette	292,027	100,636
L'Anse	13,308	9,602
St. Ignace	7,499	.....
Total	838,582	416,268

DETROIT.—This mine, says the Marquette *Mining Journal*, is coming to the front rapidly as a steady and profitable producer. With wholly inadequate machinery, they are now raising between 60 and 70 tons a day, which product will be increased to at least 100 tons the coming week—just as soon as sufficient room is made at the bottom of the shaft for an increased force of miners. West of the most westerly pit, a shaft is going down in ore of very fine quality.

NONESUCH.—The managers have been engaged for some time in what turns out to be an impracticable metallurgical treatment of the peculiar deposit-matter afforded by the mine. The attempt to recover the copper in the rock by reducing it by means of rollers and then subjecting it to lixiviation and precipitation has been abandoned, and if mining operations are continued, the usual method of crushing and dressing in the district will be adopted.

PHŒNIX.—The largest creditors of this mining company, says the Houghton *Mining Gazette*, reside in the district and offer to work the mine for the purpose of paying off the local debts of the corporation, which chiefly consist of labor liens.

QUINCY.—The stamp-mill, after a thorough overhauling, has started up again. The mill was out of service about three weeks.

ROPES.—The first stamp-mill for gold mine use ever shipped to Lake Superior has arrived, and been hauled to this mine, three miles north of Ishpeming, where the building that is to hold it is all completed.

MISSOURI.

The people of Bates County, especially in the neighborhood of Rich Hill, are in a fever of excitement over the discovery of oil. It had been generally known that Beaumont & Foote have been sinking a well for oil; and about three weeks ago, there was a rumor that oil had been struck, but the rumor was then hushed up. Later reports stated that a public test of the well would be made June 26th, at three o'clock P.M. At that hour, there were fully three hundred persons on the grounds. The engine was started, and five barrels of the crude oil were drawn up. The well was sunk 600 feet, and the oil has risen 400 feet, and is pronounced by experts to be crude oil in its purest state. A company has been organized, and other wells will be sunk immediately. Great excitement prevails, and property is rapidly advancing in value. All the adjacent land had been quietly leased for a period of twenty years before the announcement was made that oil had been struck.

MONTANA.

DEER LODGE COUNTY.

The Philipsburg Mining District, in which little work has been done for some years, and in which little deep development has been going on lately, has entered upon a new lease of active life and is having a genuine boom. This fact is owing in a great degree to the recent developments on the Granite Mountain in tunnel No. 2. The tunnel has a total length of a little more than 1000 feet. The pay-ore was first encountered at a distance from the face of about 900 feet, from which point the ore has preserved a uniform width of three feet, increasing in many places to five for a length of 130 feet. Within a few days, 500 tons of $500 ore will be shipped to Cheltonham, near St. Louis, for reduction in the Harrison works.

LEWIS & CLARKE COUNTY.

One of the notable events of the coming Fourth of July will be the departure from Helena of a special train by the Northern Pacific, freighted with 1,000,000 pounds of Gregory and Wickes bullion, to Newark, N. J., arrangements to this effect having been consummated. The greater portion of this bullion is now stacked up at the depot. The Wickes works, which will soon start up again with increased capacity for the treatment of ores, will yield fully as much, and when the mines of Ten Mile, Red Mountain, and other neighboring districts are opened up, the Northern Pacific will find large business in the carrying trade of bullion.

NEVADA.

Late mail advices report as follows:

EUREKA CONSOLIDATED.—Affairs in the mine and shaft as usual. Our furnaces running, and producing as heretofore. Shut down No. 3 furnace on the 13th for repairs. Following is the prospect-work done during the week: Third level, uprise in quartzite, 20 feet; in all, 20 feet; Locan shaft, sunk this week, 15 feet; in all, 1194 feet.

HALE & NORCROSS.—The prospect is favorable, but in the hasty development the managers overlooked proper ventilation, the lack of which now delays work.

SUTRO TUNNEL.—The report for the week ended June 15th is as follows: Main tunnel and sub-drain between 18,724 and north lateral. Since last report, the miners employed on the drain have excavated 75 feet and cleared out and enlarged 165 feet more, and placed most of the boxes in position below the level of the track. Flow of water equal to 7,951,500 gallons per 24 hours. The following temperatures were taken: Tunnel entrance, air, 76 degrees; water, 114; shaft No. 1 east, 85; No. 1 west, 88; No. 2 east, 89; No. 2 west, 55; No. 3, 88; No. 4, 91; Combination shaft connection, 83; Osbiston shaft connection, 100; C. & C. shaft connection, 80.

UNION CONSOLIDATED.—It is the general belief that the Union Consolidated cross-cut at the 3000 level will prove a failure, although on the 2900 level feet of ore lay near the west walk.

NEW MEXICO.

The Atchinson, Topeka & Santa Fé Railroad has decided to build a branch from Socorro to the Magdalena Mountains, thirty miles west. One hundred workmen have begun work on the grade. Seventy-five men have begun work on Billings's smelter, which is to be one of two stacks with a capacity of 100 tons.

Silver City is the direct center of a large and important mining district which is located upon the surrounding hills. This includes the celebrated Bremen or 76 mine, 1½ miles distant, which has produced in the last few years nearly $2,000,000. The Sherman mine, one half-mile from Silver City, is also worked, and has furnished mill-runs of $250 per ton. Other mines are Two Ikes, Texas, Legal Tender, No Issue, Old Timer, and others. Just below the city are three stamp-mills, and a concentrator and a smelter are soon to be erected. The center of a large and prosperous mining district, of a great live stock and agricultural region, Silver City is also the county-seat of Grant County, the center of from thirty to forty mining districts, and the metropolis of the new Southwest. The most important mining districts tributary to Silver City and their distances from it are as follows: Silver Flat, one mile southwest; Chloride Flat, two miles west; and Pinos Altos, seven miles north.

NORTH CAROLINA.

Much attention is now directed to gold mines in this State, and an exhibition of the metal is to be made at Boston next autumn. Northern men are pouring into the State prospecting, and there are rumors of large finds. Large quantities of machinery, stamp-mills, etc., are arriving.

A recent report states that a company has been incorporated at Charlotte, with a capital of $2,000,000, for the purpose of conducting gold mining in the State on an extensive scale. The property of the company embraces twenty-two gold mines, varying in the value of their assays. Heretofore, it has cost about $2 for every dollar's worth of gold mined in North Carolina; but the new company claims to have a new process whereby it will save 95 per cent of the gold, and make it a paying business.

UTAH.

EMMA.—The drift from the 130-foot station is nearing the interception of the bottom of the incline run down from the Bay City tunnel until it was drowned. It is expected to strike it at or a little below the bottom. The drift is in vein matter. It is intended to continue the shaft to a greater depth, and at suitable intervals drift across the vein and then open levels. A level is to be run on the 130-foot. The machinery is said to be competent to do the work and take care of any probable amount of water. While the mine may be a wet one, it is not likely to be very wet, the tunnel catching and draining off all the surface-water.

FRISCO.—It is said there are in this mine two feet of galena ore that will go 110 ounces in silver and forty-five per cent lead. There are eighteen inches to three feet of ore in every place that is worked. Another shipment of ore will be made as soon as the snow gets out of the upper gulch.

FRISCO MINING AND SMELTING COMPANY.—At the Cave mine, the property of this company, a rich vein of three feet of ore has been recently struck, going 300 ounces of silver, 3 ounces of gold, and 25 per cent of lead. The richest ore lies above a vein of native sulphur, in some places two feet thick. The sulphur is mixed with gray carbonate, and is very rich. There are fully 11,000 feet of tunneling and drifting in the mine. The main tunnel is in 1300 feet. The mine is not shipping ore at present. The smelter is lying idle. Twenty men are employed, who are thoroughly prospecting the mine.

HORN-SILVER.—The old stacks have been demolished and the ground and part of the dump has been cleaned up. The result was a few car-loads of good bullion. The 600-level of this mine holds out well, the lowest workings, however, showing a tendency to run in copper.

MAMMOTH.—Much to the regret of all mining interests, says the Salt Lake *Tribune*, this great property at Tintic has finally settled into very bad shape. The projectors of the enterprise seem to have dropped it, for the present at least, and all hands seem determine to have a clean-up in the courts before any more real work is done.

MARDOCK REDUCTION-WORKS.—The Ogden *Pilot* states that these works are to be put in operation at Ogden.

ONTARIO.—Shipments have been resumed since the mill clean-up. The great tunnel from the mill to the mine is making swift progress, and is expected to be completed by September, when the pumping of water will be less troublesome for some time to come. During the spring freshets, the lower levels were in imminent danger of being drowned out.

SILVER REEF.

BARBEE & WALKER.—The mine is worked by Gillespie, Lund & Co., employing sixteen men. The mine has an incline shaft 500 feet deep. They are sinking a winze below the fifth level about thirty-five feet, having five feet of ore. Considerable stoping is doing on the third, fourth, and fifth levels. The ore is looking well, there being about 250 tons on hand. The mill is expected to start soon.

CHRISTY.—The company is working its mines steadily, showing great improvement in the quality of the ores. The five-stamp mill steadily pounds away, averaging about fifty pounds daily.

LEEDS.—At the Leeds mill, J. A. Turrill is working the tailings, and is meeting with success, turning out every six days a bar of bullion valued at $1200.

STORMONT.—The company is milling 1200 tons of ore monthly. It is working 50 men in the Savage, Buckeye, and Last Chance—all being worked through the same vertical shaft, 250 feet deep. The deepest workings are on an incline from the foot of this shaft at a depth of 175 feet; from this point, the fifth level extends north and south. The best body of ore lies at the south end of this level. This is a continuous body of ore that has been followed from the croppings down a distance of 750 feet. The present appearances are, that the quality and quantity of ore is getting better. Sinking is about to be commenced on the sixth level. The ten-stamp mill belonging to the company runs sixteen hours daily, milling sufficient ore to be worked by seven settlers and thirteen pans.

Under date June 18th, Superintendent Allen writes from Silver Reef: In winze 15, we are down 41 feet, and have good ore all the way, with an unusually well-marked hanging wall, a favorable indication for the continuation of ore. Assays from the face yesterday showed 26 inches of $140 rock.

WYOMING.

According to the local papers, the mines in Silver Crown District are now worked with an energy well worthy of Western enterprise. On some of them night and day shifts are employed. The owners have had much to contend with in the past, but their perseverance has even now well-nigh brought them their reward. While the ore in the main is of low grade, there are found rich "pay-streaks," some of which assay very high; and if the anticipations of those interested are realized, it is confidently expected that a smelter will be in operation in the district within the next year.

The new discovery located on the Rabbit Ear range of mountains is situated in Red Cañon, about ninety miles from Laramie, in a country which has never yet been prospected. Numerous assays and tests of the ore have been made, and it runs high in copper, and $16 in gold, and $5 silver. This is from the surface, comparatively; for no considerable depth has been reached. It is the intention to sink about six shafts of forty feet each on the two claims, and, if the mines then warrant it, a smelter will be put in. Six men are at work on the mines.

G. Gold. S. Silver. L. Lead. C. Copper. * Non-assessable. † Stocks quoted on S. F. San Francisco; B., Boston; P., Philadelphia. Non-Dividend shares sold, 82,700. Total shares sold, 138,740.

an active business at steady prices; it sold from 19@21c.

The Leadville stocks record a moderate business at steady prices. Amie was quiet and a little weak, selling from 18@16c. Chrysolite was steady at $1.15, the sales amounting to 300 shares. Dunkin sold at 20c., and Hibernia at 4c. Iron Silver had a small business at steady prices, selling from $3@2.95. Leadville sold at 56c., with one transaction. Little Chief was quiet and a little weak, selling from 57@58c. Little Pittsburg declined from its strong prices of last week, selling from $1.10@99c., with a fair business. Climax showed a little strength and activity; it sold from 8@13c.

The Bodie stocks were quiet at weak prices. Bodie Consolidated sold from $1@98c. with a small business. Standard was quiet and strong, selling from $6.63@$7. Bulwer has been weak, under moderate transactions, selling from 85@75c. Goodshaw sold at 4c., and North Standard sold at 10c.

The favorites of the Tuscarora stocks were strong, while the low-priced stocks were generally weak. The business done in them was small. Belle Isle had a fair business at irregular prices, selling

Digitized by Google

from 50@60@54c. Navajo showed considerable strength, selling from $2.35@$4.15, with a small business. Independence was quiet and strong, selling at $1. Grand Prize has levied an assessment of twenty-five cents, and was, in consequence, quite weak, selling from 30@12@16c., with small transactions. Argenta was quiet and weak, declining from 30@20c. Elko Consolidated has been active and weak, selling from 31@20c.

In the miscellaneous list, Alice was quiet and steady at $2.50. Caribou was steady at 13c., the transactions being small. Eureka Consolidated has been very strong, under a small business, selling from $4.90@$8. Horn Silver has gained some strength, under a fair business, and has sold from $6.63 @$7.75@$7.50. Northern Belle was quiet and strong to-day, selling from $6.88@$7. The company has passed its usual monthly dividend. Ontario, with a small business, has been irregular, selling from $26⅛@$27@$26¼. Robinson Consolidated records an active business at irregular prices; it sold from 50@61@56c., the business aggregating 15,200 shares. Sierra Grande was active and irregular, selling from $1.20@$1.45@$1.25. Silver King had a small business at steady prices, selling at $10.25. Stormont was quiet and strong, selling from 20@40c.

Alta-Montana has been quiet and weak at 2c. Bradshaw sold at 31@30c., with small transactions. Caledonia sold at 85c. Central Arizona was quiet and steady, selling from 27@30c. Decatur had a small business at steady prices, selling at 5@4c. Durango sold at 7@6c., the business being small. Eastern Oregon was active and strong, selling from 48 @57c., the transactions aggregating 10,900 shares. Harlem was quiet and steady at $1.40. Oriental & Miller sold at 15c. with a small business. Rappahannock sold from 9@7c. Sonora Consolidated had an active business at weak prices; it sold from 23@18@ 19c. Parnell is the name of a new stock dealt in for the first time this week; it was quiet and irregular at 45 @42@44c. The property of the company consists of twelve mining claims located on London Mountain, Mosquito District, Park County, Colorado, and is on the same mineral lode as the London Mining Company's property, which has proved quite valuable.

PIPE LINE CERTIFICATES.

The petroleum market opened very dull this week; and up to Thursday, the fluctuations were of a very quiet character, with a tendency to lower prices. On Thursday, there was an active spurt in the market, and the price closed stronger than for some days past. To-day, the price has been strong and the market active.

The news from the oil districts states that on Monday last the new Grandin No. 9 well was yielding 225 barrels a day, the Balltown No. 3 was flowing at the rate of twenty barrels an hour, and the Porcupine No. 6, after being torpedoed, was flowing at the rate of 150 barrels. Thursday, it was reported that the production of the Balltown District for the last twenty-four hours was 2504 barrels from twenty-two producing wells, against 2931 barrels on last Friday. There are six wells drilling and eleven rigs up and building in this district. With no permanent increase reported in the productiveness of the oil regions, the pipe line runs continue to exceed the deliveries, and to June 26th the figures are: Runs, 1,700,847 barrels; average per day, 65,417; deliveries, 1,534,222; average, 50,009; excess runs, 166,625 barrels; average per day, 6408 barrels. To-day's reports state that Balltown No. 7 well is flowing 80 barrels from the top sand; but owing to disputed ownership, it will not be opened at present. It is now stated that the monthly report will be more favorable than was expected, and that it will show a marked decline in developments. There are now only eight wells drilling in and around the Cooper tract, and the production is dropping rapidly.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

		Opening.	Highest.	Lowest.	Closing.	Sales.
June	23....	$1.16⅞	$1.16⅞	$1.15½	$1.15⅝	1,438,000
	25....	1.15½	1.16¾	1.15½	1.16	1,495,000
	26....	1.16⅛	1.16⅝	1.15⅝	1.15⅞	1,142,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, June 28.

The market for copper stocks continues to rule extremely dull and inactive, the sales for the week hardly amounting to a respectable day's work in ordinary times. There is no pressure to sell stock, neither are there any orders to buy, and consequently business lags, and brokers' commissions are few and far between. Calumet & Hecla sold at $242, at which price any offered is taken. Quincy declined from $49@$48, while Osceola advanced from $19½@ $21, but subsequently declined to $20, at which it is freely offered. There were no sales of Franklin, and only 200 shares of Pewabic sold at $31½@$32, buyer 60. The latest report from the Pewabic is to the effect that a mass of copper of about twenty-five tons was thrown into the opening last week. At the Quincy, the stamp-mill has resumed operations, and the product for June will be fully up to the average output.

The silver stocks are more active, and at the Mining Exchange, there seems to be a revival of the old-time vigor under the lead of Bowman Silver Mining Company, which is the card now, and which fluctuates enough to satisfy the most ardent speculator. The stock closed last week at 42c., from which it declined to 27c. Subsequently it advanced again to 39c., closing yesterday quite strong at 37@38c. This morning, a flood of stock coming on the market sent the price back again to 27@28c. The desire on the part of the shorts to cover strengthened the market, and it closed quite steady at 31@32c. Massachusetts & New Mexico, which has been dull and inactive at 7c., also felt the influence of the better market, and advanced to 9c., at which price about 20,000 shares were marketed. The prospects of the company are more encouraging, and it is quite reasonable to expect the stock to advance to much higher figures. Catalpa has been fairly active; advancing during the week from 60@67½c., with a decline later to 62½c. Sullivan sold at $1⅞@$2. Silver Islet declined to $3; and San Pedro sold at 40c.

3 P.M.—The market was dull this afternoon. A single share of Calumet & Hecla sold at $240. San Pedro declined to $32½. Franklin, $10 bid. Pewabic, $32¼ bid. Quincy offered at $48. Atlantic offered at $12, no bid. Osceola offered at $20. Huron, $1¼ bid. National, $1⅛ bid. Silver Islet, $3 bid. Sullivan, $1½@$1⅞. San Pedro, 30c. bid. Bonanza, $2⅛@$2¼.

BULLION MARKET.

NEW YORK, Friday Evening, June 29.

The rise in the exchanges in India, which caused the recent advance in silver in London, has been lost within a few days, and the market has receded, as shown by the figures of the annexed table, and may be regarded as in suspense for the present.

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.
June 23	50¾	110¾	June 27	50⅛	110⅛
25	50 11-16	110¾	28	50 7-16	110⅛
26	50 9-16	110½	29	50 7-16	110⅛

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended June 29th, as compiled from various sources, amounted to $138,500, as against $131,000 reported for the previous week. The receipts from January 1st, 1883, to date are $5,830,213.53.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended June 23d	$351,100
Corresponding week last year	1,447,052
Since January 1st, 1883	6,405,704
Corresponding period last year	34,295,437

Imports.

Week ended June 23d	$104,240
Corresponding week last year	46,764
Since January 1st, 1883	6,893,465
Corresponding period last year	1,915,406

Foreign Bank Statements.—The governors of the Bank of England, at their regular weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 4 per cent. During the week, the bank gained £346,000 bullion, and the proportion of its reserve to its liabilities was raised from 41 to 41 5-16 per cent, against 43 per cent at this date last year. June 28th, the bank made a further gain of £75,000 bullion on balance. The weekly statement of the Bank of France shows losses of 1,154,000 francs gold and 1,144,000 francs silver.

METALS.

NEW YORK, Friday Evening, June 29.

Copper.—Beyond trifling sales of a jobbing character, there is nothing to report. Lake is nominally 18⅛@18¼c., and other brands 14@14⅛c. England cables, f. o. b., Chili Bars, £64 10s.; and Best Selected, £70; prices, therefore, being very well maintained there.

Tin.—*Business is picking up.* There is a good jobbing demand, and the spot stocks are concentrating in a few strong hands. We quote spot Straits and Malacca, 21⅛c.; Australian, 21⅝@21¾c., with sales at 21⅝c.; Banca, 22c.; and Lamb & Flag, 21¼c.

Lead.—Our market has remained dull and featureless. It seems that manufacturers have pretty well supplied themselves by purchases for future delivery, and the fear is expressed that stocks may accumulate here unduly. The business in Refined lead for the year thus far has been exceptionally light in the East. Spot lead is freely offered at 4·40c.

We note sales of about 500 tons of Common and some Refined, for August delivery, at 4·40c, 4·42½c., and 4·45c.

Messrs. John Wahl & Co., of St. Louis, wire us as follows to-day:

Our market is unchanged. We quote refined 4·13c. Of Hard lead, there have been no sales; it is quoted nominally at 4·12½c. Refined is offered at 4·15c. for July delivery.

Messrs. Everett & Post send us the following dispatch:

There has been considerably more inquiry for both Hard and Soft lead, and though only little business has been done, sellers ask a slight advance. Sales aggregate 650 tons of Common and Refined at 4·15c. and 4·20c. We close nominally 4·17½c. and 4·20c.

Spelter.—The market continues dull, with little business transacting. Quotations are nominally 4·50 @4·60c. for good ordinary Domestic.

Antimony.—The feeling is a trifle better, notably so far as Cookson's is concerned, which we quote 10½ @10⅝c., while Hallett's is less firm at 9½@9⅝c.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, June 29.

American Pig.—The improvement in the standard grades of foundry pig noted in our last has gained in strength, and the best brands of No. 1 are now held at $23@$23.50 for delivery in September and October. We may note, as showing an increasing interest in the Metal Exchange, that there were sold there to-day 800 tons of No. 1 Pig at $23 and $23¼ for September delivery, and $23½ for October delivery. Furnace agents report sales of upward of 8000 tons, the bulk of it Thomas No. 2 and Forge, at $20 and $19. The Thomas Iron Company now declines to sell even to regular customers at former figures, and quotes $20 and $22 now for No. 2 and No. 1 Foundry. The heroic cure, against which there were so many vehement protests, has brought a healthier tone into the market much earlier than it would have been reached by a lingering period of gradual weeding out of the weak elements. Thus far, the improvement is confined to No. 1, which we quote $21@$23 good to choice grades, spot cash at tidewater. No. 2 is worth $18.50@$20 and Gray Forge $18@$19.50. Bessemer Pig is quiet at $21 asked, foreign cables being 50@51s. Spiegeleisen is dull and quiet, with quotations at $31.50@$32 for 20 per cent, $47@$48 for 40 per cent, and $25.50@$26 for 10 to 12 per cent.

Scotch Pig.—Business here has been of a restricted character, though there is a more hopeful feeling, in sympathy with the better tone in the higher grades of American pig. The arrivals continue at the average scale, about 1000 tons per week, while freights are firm at 7s. 6d.

At the Exchange, the following cable quotations were received yesterday: Coltness, 60s.; Langloan, 59s. 6d.; Summerlee, 57s. 3d; Gartsherrie, 57s. 6d.; Glengarnock, at Ardrossan, 54s.; and Eglinton, at Ardrossan, 48s. Warrants to-day were 47s. We quote here, all ex ship, Coltness, $24@$24.50; Langloan $24; Summerlee, $23.50@$24; Gartsherrie, $23.50 @$24; Glengarnock, $22; and Eglinton, $21.

Rails.—During the week, one order has been placed of 10,000 tons at $37.50 at mill, and another order for the same amount is on the market, both we understand, for fall and early winter delivery, for which

Digitized by Google

$37.50@$38 may be considered the ruling quotation, though some buyers seem unwilling to go so high. For summer delivery, a few small lots may be placed at $38@$38.50 at mill. England cables £4 15s.@ £4 17s. 6d.

Old Rails.—The market is quiet and dull, with bids at $21@$21.50 for Ts.

Scrap.—We have no business of consequence to report, the market remaining dull at $22.50@$23 for No. 1, ex ship.

Philadelphia. June 29.

The situation of the Eastern Pennsylvania iron trade has not improved during the past week, on account of the closing of the season and the indisposition of large buyers to enter into any contracts for summer or fall requirements. There are no special causes depressing the market, but a wholesome conservatism prevails in iron-trade circles, growing out of the happenings of the past sixty days. Things have not gone exactly as was expected. If the necessary restriction of output takes place, those who stay to enjoy the trade will find no trouble in maintaining remunerative rates; but should all conclude to stay and divide the business, there will be a vigorous and unhealthy competition, which will for a while retard demand, rather than stimulate it. The full output in the West is the chief disturbing factor in the iron trade. The manufacturers of specialties there possess some advantages which enable them to crowd down the plain bar manufacturers East on prices. The fraternal feeling generated in consequence of this operation of competitive forces is not overwhelming. Leading manufacturers, in summing up the half-year's work, say that, on the whole, it has been as good as the average of six or seven years past, and that the indications for the midsummer and fall trade are satisfactory to them. There is a fair run of orders. Prices have been well maintained. The demand is widening, and there are no special reasons for anticipating any sudden breaking-up of the favorable conditions surrounding the trade. To what extent restriction may become necessary is a problem which will be determined in a few weeks. Meanwhile, bar mill men will repair, take stock, settle up, and wait to see what will be developed. Unless iron can be made at present cost and sold at present prices, there will be no strong inducement to begin soon. A great deal of Bar iron has been selling within a few days in a small way, at 2·10@2·15c., and only the finest makes command more. The storekeepers report a fair run of retail trade. Country mills are, in some cases, short of orders, and hence the competition referred to. Others have some orders for car iron, which will last them a few weeks. The railroad requirements are a strong support to the trade, and a good deal of iron for such purposes will be needed before winter. Inquiries have been made for 100-ton lots for July and August, but in most instances heard of, nothing was consummated, as manufacturers see no room for further concessions so far ahead.

Pig-Iron.—Brokers are not doing much excepting in No. 1 Foundry. This is scarce, and the special brands seem to be either sold up or virtually contracted for by regular customers. The limit of prices is about $20@$23.50 at shipping port, although in some few cases less and more have been taken. The supply of No. 1 is short in makers' hands, and consumers seem to have permitted stocks to run unnecessarily low, and the makers think they will pay the penalty before the summer is over, as the output is not as great as in cold weather. No. 2 has been the football of the market for some weeks, and is now developing more strength, reflected on it by the greater firmness of No. 1. Foreign irons are not worthy of a line this week.

Plate and Tank Iron.—The business in sight for July, if secured, will satisfy the successful competitors for a few good lots of iron. As a general thing, plate is bought in small lots, on account of the notion of buyers and contractors that present prices are not the lowest. Tank ranges from 2·30@2·40c.; Shell, 3@3·25c.; Flange, 4@4·10c.

The boat-yards and ship-yards and some locomotive-works have been making inquiry for a good deal of iron to be delivered through the summer.

Structural Shapes.—Quotations are, for Angles, 2·4[illegible]c.; Beams and Channels, 3·20c., with concessions on heavy orders, which are rare. The situation at the mills is satisfactory, and a busy summer is assured. Inquiries for a few large lots are on the market, but will not be placed until after next week.

Sheet-Iron.—All the sheet-iron manufacturers are busy, and some of them have gathered up enough orders to last them over summer. Consumptive requirements are large enough for the capacity, and hence makers say that prices will remain about where they are. Card rates are 4@4½c., though retail lots command a little more. Large orders are taken at less. Galvanized is 40 per cent off for best, and 35 for next best. Shipments for the last few days have been unusually large.

The hardware trade is doing very little at present outside of the usual season goods, which are in active demand.

The discounts on wrought pipes are 70 per cent, and on tubes, 57½@60, and large manufacturers report business mostly of a retail character.

Old material is without any activity. Steel rails are firm on reported quotations, and, after the turn of the season, manufacturers look for large orders for winter delivery. Cargo Scrap, $23; English Tees, $22, without sale; Double-Heads, $25@$26; Selected Scrap, $24.

Pittsburg. June 28.

The undertone of the Western Pennsylvania iron market is less satisfactory than last week. Leading manufacturers, interviewed with reference to the prospects of the trade, express the opinion that there is very little improvement to be hoped for, as long as the present output is maintained; that the policy of full production is at variance with the interests of the iron trade; and that a reaction will take place, sooner or later. Business is dull in all departments. Current requirements have been restricted, and transactions with reference to future requirements are extremely rare. Something of the nature of a shut-down is believed to be necessary, and this will be inaugurated next week, by the going out for the repairs incident to the season. The local furnaces supply the mill requirements, and stocks are accumulating at the valley furnaces. A further restriction in the output of both furnaces and mills must take place.

Gray Forge Iron, lake ore, $17; Bessemer, $21.50; No. 2 Refined, $18.50; White and Mottled, $16@$17. Muck Bar is extremely dull at nominally $34. Some mills on Merchant Iron have stopped, and some will shut down in a few days. Ordinary quotations are 1·90@2c., but sales have been made as low down as 1·75c. in occasional cases. Shipments of nails have been made from Pittsburg and Wheeling. Stocks are light, and prices firm at $2.90@$3. Steam Pipes are 70 and 10; Boiler Tubes, 55 and 5. Oil-well Casing, 45@50c. per foot. Heavy shipments of Steel Rails are made by river, and new orders are coming in at $38.50. Old Rails are in active request, and are selling freely at $22.50@$25. Scrap is without any activity whatever. The trade is at a standstill, and nothing but a general rest will improve prices.

Cleveland. June 26.

We have nothing special to note for the past week, the situation remaining about the same. While there is no real advance in prices, the tendency is upward. Western furnaces very generally expect to blow out; this would undoubtedly in a measure help Eastern furnaces. There has been more ore sold for the past week than for a corresponding period for some time. We quote:

No. 1 Bessemer	$21.00@$22.00
" 1 Foundry, all ore	20.00@ 21.00
" 1 Foundry, cinder mixture	19.00@ 20.00
" 1 Soft Foundry	20.00@ 21.50
" 1 Open Silvery	19.50@ 20.00
Mill irons	18.00@ 19.00
4 months f. o. b. cars furnaces.	
Nos. 1 and 2 Charcoal	$24.00@$26.00
" 3, 4, 5, and 6 Charcoal	25.00@ 26.50
Hanging Rock Charcoal	23.00@ 25.00
Strictly Cold-Blast Charcoal	25.00@ 30.00
4 months f. o. b. cars Cleveland.	
Bessemer ores	$7.00@$8.00
Hematite ores	5.00@ 6.00

COAL TRADE REVIEW.

NEW YORK, Friday Evening, June 29.

Anthracite.

There is some activity shown by commission men and dealers to secure coal at present prices, and some of the companies report heavy sales. In other quarters, the market is quiet. There is little doubt now that the advance noted previously will be asked, but it remains to be seen whether it will be generally secured.

The following figures will be of interest to the trade as showing what wide differences exist among some of the companies in promptly shipping their coal:

Port Richmond, Philadelphia & Reading Railroad.

	Tons.
Shipments to November 30th, 1882	2,017,896
Of which wheeled (41 per cent)	841,805

Perth Amboy, Lehigh Valley Railroad.

	Tons.
Shipments to November 30th, 1882	1,791,755
Of which wheeled (19·57 per cent)	350,631

Port Johnson, Lehigh & Wilkes-Barre Coal Co.

	Tons.
Shipments to November 30th, 1882	1,417,662
Of which wheeled (9 per cent)	129,274

South Amboy, Lehigh Pier, Pennsylvania Railroad.

	Tons.
Shipments to November 30th, 1882	486,614
Of which wheeled (40·3 per cent.)	196,158

South Amboy, Wyoming Pier, Pennsylvania Railroad.

	Tons
Shipments to November 30th, 1882	347,323
Of which wheeled (32·3 per cent.)	112,019

Harbor freights show a tendency to stiffen, while Eastern freights are less strong.

Bituminous.

There is nothing of interest to report. Current business is still remarkably slack, and concessions appear to be freely made.

STATISTICS OF COAL PRODUCTION.

Comparative statement of the production of anthracite coal for the week ended June 23d and year from January 1st:

TONS OF 2240 LBS.	1883. Week.	1883. Year.	1882. Week.	1882. Year.
Wyoming Region.				
D. & H. Canal Co..	99,563	1,702,682	84,172	1,539,120

North & West Br. RR.	7,302	216,355	.....	.....
	381,856	6,557,438	328,248	6,008,762
Lehigh Region.				
L. V. RR. Co.....	116,291	2,217,080	117,131	2,171,322
C. RR. of N. J.....	62,148	1,059,302	55,340	996,574
S. H. & W. B. RR..	1,783	23,680	.....	20,000
	180,222	3,300,062	172,471	3,187,896
Schuylkill Region.				
P. & R. RR. Co.....	181,762	3,138,081	175,939	2,922,568
Shamokin & Lykens Val.....	34,874	624,543	29,252	546,017
	216,636	3,762,624	205,191	3,468,585
Sullivan Region.				
St Line&Sul.RR.Co.	1,677	29,117	1,627	27,070
Total	780,391	13,649,241	707,537	12,692,313
Increase.....	.....	2,956,928	.....	.....
Decrease.....	.....	.....	.....	.....

The above table does not include the amount of coal consumed and sold at the mines, which is about six per cent of the whole production.

Total same time in 1878	7,212,065 tons.
" " " " 1879	12,033,998 "
" " " " 1880	10,321,876 "
" " " " 1881	12,577,684 "

The increase in shipments of Cumberland Coal over the Cumberland Branch and Cumberland & Pennsylvania railroads amounts to 330,060 tons, as compared with the corresponding period in 1882.

Belvidere-Delaware Railroad Report for the week ended June 23d:

	Week.	Year. 1883.	Year. 1882.
Coal for shipment at Coal Port (Trenton)	4,617	42,860	29,075
Coal for shipment at South Amboy	21,127	390,842	372,999
Coal for distribution	17,392	374,414	332,862
Coal for company's use	2,868	70,400	61,340
Total	45,004	878,516	796,876
Increase	.....	81,640	.....
Decrease	.....	.....	.....

The Transportation of Coke over the Pennsylvania Railroad for the week ended June 23d and year from January 1st:

Tons of 2000 lbs.	Week.	Year.
Penn. RR. (Alleghany Region)	526	49,426
West Penn. RR.	2,003	51,413
Southwest Penn. RR	42,742	988,194
Penn. & Westmoreland Region, Pa. RR	4,066	110,196
Pittsburg, Penn. RR	31	454
Snow Shoe (Clearfield Region)	489	9,971
Total	49,857	1,189,654

THE United States Association of Charcoal Iron-Workers will hold its next meeting at Detroit, Mich., beginning August 13th.

MR. SYDNEY GILCHRIST THOMAS, the inventor of the basic process, sailed for England to-day, after a very brief stay in this country. He has been traveling in India and Australia for his health.

THE thirty-second meeting of the American Association for the Advancement of Science will be held at Minneapolis, Minn., from August 15th to August 21st. Hon. GEORGE A. PILLSBURY is chairman and Prof. N. H. WINCHELL secretary of the local committee.

WE print elsewhere an abstract of a paper by Mr. PARKER, of Lloyd's, on steel castings for ship-building purposes, which apparently closely reflects the opinions held by the most prominent steel-makers and metallurgists abroad on the important subject of casting steel. In our own country, in a quiet way, considerable progress has been made during the past few years ; and for a great number and variety of purposes, steel cast directly into the form in which it is to be used has found a ready application. Any one acquainted with the valuable properties of steel, and knowing the cost of shaping it by machine tools into the desired form, will fully appreciate what a great end those who are devoting attention to this subject are working for. There are two obstacles which must be overcome : the first to produce dense castings free from blow-holes and other defects ; and the second, to give them at once a finish that will approach the smoothness of good iron castings. Success in meeting the latter and, to some extent, the former requirement hinges upon the selection of a suitable material for the mold. The earlier methods of making steel castings were those of REPEE, who sold his patent to the VICKERS, of Sheffield, England, and of HAINSWORTH, of Pittsburg, under whose patents a number of establishments in this country are working. The first consists in making molds from old clay crucibles, pulverized, with an addition of twenty per cent of black-lead, baking them in a furnace, and coating them with coal-tar, the steel being poured into them while still hot. The principal objection to the Repee process and to all other molds in which carbon is largely used, is, that it is impossible to make castings of soft steel. As soon as the hot metal comes into contact with molds made of such mixtures, it absorbs a portion of the carbon. The Repee castings, too, are not smooth, and require considerable grinding and chiseling, or "fettling," as it is called in England ; and though all such castings must be annealed before use, their surface nevertheless lacks ductility. With a view to remedying these defects, Mr. GEORGE COWING, of Cleveland, a number of years ago made a series of experiments at the Otis & Cleveland Rolling-Mill Company's steel mills, during the course of which two points of importance were brought out. It was found that the ordinary molding materials would not stand the heat of liquid steel without fluxing more or less, so that the castings produced were always heavily coated with scabs and slag, and were filled with blow-holes caused by the impossibility of allowing the gas to escape through the walls of the mold. Mr. COWING found that the best material meeting these objections was one which contains a maximum amount of silica and an immense quantity of substances capable of causing fluxing. He uses the purest quartz or sand, roasts it, and stamps it to an almost impalpable powder ; and in order to permit handling the mold, moistens it with thin glue-water to the temper of ordinary molding-sand.

Experience in nearly all of the large works of the United States and several of the most noted establishments of England, during the past four years, has thoroughly demonstrated that solid and smooth castings can be made in the Cowing silica molds from any grade or variety of steel. Castings have been made in these molds from Bessemer, Siemens-Martin, and crucible steel. At the Otis works in Cleveland, mild steel having but one tenth per cent of carbon has been cast in them into articles that have been bent double without annealing. Liquid steel of this character is the hottest metal known to metallurgy ; and yet it apparently makes no impression on the silica molds, the castings coming out of the sand bright and so clean that no work is required on them, further than a good brushing. We understand that at the present time twenty-three of the largest steel plants in the United States are making steel under the Cowing patent, and two special plants are now going up to make castings by this method : one, by Messrs. JOHN ROACH & RYDER on the Delaware, and another, of which Mr. S. T. WELLMAN, of Cleveland, is at the head, at Alliance, Ohio. Messrs. ROACH & RYDER intend to use the process largely in making heavy castings to take the place of forgings, such as armor plates, shafts, cranks, etc., for vessels.

It will be seen, therefore, that American engineers and iron-masters have not been idle, and that they are fully awake to the difficulties of the problems presented, and are rapidly progressing toward the attainment of this important end.

EDITORIAL CORRESPONDENCE.

The New Rocky Mountain Line.

Having just made the trip from Salt Lake City to this place by the Denver & Rio Grande line, I can not write you on any other subject at present. There is not in the world a railroad journey of thirty hours so filled with grand and beautiful views. I should perhaps qualify this statement by deducting the hours of darkness ; yet this is really a fortunate enhancement of the traveler's enjoyment : it seems providential, that there is one part of the way, just long enough and uninteresting enough to permit one to go to sleep without the fear of missing any thing sublime. Leaving Salt Lake City at noon, we sped through the fertile and populous Jordan Valley, past the fresh and lovely Utah Lake, and up the valley of Spanish Fork. All the way, the superb granite walls and summits of the Wahsatch accompanied us on the east, while westward, across the wide valley, were the blue outlines of the Oquirrh range. One after another of the magnificent cañons of the Wahsatch we passed, their mouths seeming mere gashes in the massive rock, but promising wild and rugged variety to him who enters—a promise which I have abundantly tested in other days. Parley's Cañon, the Big and Little Cottonwood, and, most wonderful of all, the cañon of the American Fork, form a series not inferior to those of Boulder, Clear Creek, the Platte, and the Arkansas, in the front range of the Rockies.

Following Spanish Fork eastward so far as it served our purpose, we crossed the divide to the head-waters of the South Fork of Price River, a

Digitized by Google

tributary of Green River. It was a regret to me, in choosing this route, that I should miss the familiar and beloved scenery of Weber and Echo cañons—the only part of the Union Pacific road which tempts one to look out of the car-window, unless one may be tempted by the boundless monotony of the plains or the chance of a prairie-dog. Great was my satisfaction, therefore, to find that this part of the new road, parallel with the Union Pacific, but a hundred miles farther south, traverses the same belt of rocks, and exhibits them in forms not less picturesque. Castle Cañon, on the South Fork of the Price, is the equivalent of Echo Cañon, and its equal or superior in every thing except color. The brilliant red of the Echo cliffs is wanting. The towers and walls of Castle Cañon are yellowish-gray. But their forms are incomparably various and grotesque—in some instances sublime. The valley of Green River at this point is a cheerless sage-brush desert, as it is farther north. To be sure, this uninviting stream, a couple of hundred miles farther south, having united with the Grand, and formed the Rio Colorado, does indeed, by dint of burrowing deeper and deeper into the sunless chasms, become at last sublime. But here it gives no hint of its future somber glory. I remained awake till we had crossed Green River, to make sure that no striking scenery should be missed by sleep. But I got nothing for my pains except the moonlight on the muddy water; and next time, I shall go to bed comfortably, proving to the conductor that I am a veteran and not a tender-foot.

In the morning, we breakfasted at Cimarron, having in the interval passed the foot-hills of the Roan Mountains, crossed the Grand, and ascended for some distance the Gunnison, a tributary of the Grand, the Uncompahgre, a tributary of the Gunnison, and finally a branch, flowing westward, of the Uncompahgre. A high divide at the head of the latter was laboriously surmounted; and then, one of our two engines shooting ahead and piloting us, we slid speedily down to Cimarron. It is in such descents that the unaccustomed traveler usually feels alarmed. But the experience of the Rio Grande Railroad people is, that derailment is likely to occur on up-grades, and almost never in going down.

From this point, comparison with the Union Pacific line in the matter of scenery ceases. As every body knows, that road crosses the Rocky Mountains proper in a pass so wide and of such gradual ascent that the high summits are quite out of sight. If it were not for the monument to the AMESES, there would be nothing to mark the highest point. For all the wonderful scenery on the Rio Grande road, between Cimarron and Pueblo, the Union Pacific in the same longitudes has nothing to show. From an artistic stand-point, one road has crossed the ranges at the most tame and uninteresting point that could be found, and the other at the most picturesque.

At Cimarron, the road again strikes the Gunnison, and plunges into the famous Black Cañon. In length, variety, and certain elements of beauty, such as forest-ravines and waterfalls, this cañon surpasses the Royal Gorge of the Arkansas. There is, however, one spot in the latter (I mean, of course, the point where the turbulent river fills the whole space between walls 2800 feet high, and the railroad is hung over it) which is superior in desolate, overwhelming grandeur to any thing on the Gunnison. Take them all in all, it is difficult to say which is the finer. I have usually found the opinion of travelers to favor the Gunnison Cañon. But why need the question be solved at all? This one matchless journey comprises them both; and he who was overwhelmed in the morning by the one, holds his breath in the afternoon before the mighty precipices of the other. To excuse myself from even hinting such folly as a comparison of scenery, I will merely remark that these two cañons are more capable of a comparison than different scenes usually are; for they belong to the same type—deep cuts in crystalline rocks.

Between them come the Marshall Pass (nearly 11,000 feet above sea-level) over the continental divide, and the Poncha Pass, over the Sangue di Cristo range. This range contains Harvard, Yale, Princeton, Elbert, Massive (the peak opposite Leadville), and other summits exceeding the altitude of 14,000 feet. To the east of it is the valley of the Arkansas, into which and down which we pass, and so through the Royal Gorge to Cañon City and Pueblo, where we arrive before dark on the day after leaving Salt Lake.

Salt Lake, the Jordan Valley, Utah Lake, the Wahsatch, Castle Cañon, the Black Cañon of the Gunnison, Marshall Pass, Poncha Pass, the Arkansas Valley, the Royal Gorge—what a catalogue for so brief a journey! No wonder every body who has made it is "wild about it." If enthusiastic urgency of recommendation from every passenger has any influence (and I know it has a great deal), this road will continue to be, as it is at present, crowded with tourists. It furnishes a delightful route for those who wish on the overland journey to see Denver (as who does not?) and to visit Colorado Springs and Manitou. All this can be done *en route*, without retracing the steps.

I ought to add that a minor but highly important and agreeable surprise of this trip was the safety and comfort of it. The road-bed is excellent, and laid with steel throughout. The Pullman narrow-gauge sleepers are pretty and comfortable. The officers and servants of the company are extraordinarily attentive—a case of new brooms, perhaps: if so, may they never grow old! And finally, the eating-stations and the meals served in them are better than those on the Union Pacific, and incomparably better than those on the Central Pacific. The Denver & Rio Grande managers have pursued an admirable policy in this particular. They have erected handsome buildings for their eating-stations, and let them rent free to caterers, on the sole condition of excellence in housekeeping, purveying, cooking, and service. Failure in this respect involves summary forfeiture of lease. And finally, they have appointed a competent inspector to have charge of this particular department.

These features of management, coupled with the unique natural attractions of the road, will make it really a dangerous rival to the Union Pacific, so far as through passenger travel is concerned, at least. Already, there are signs of a bitter competition—so far, very welcome signs indeed; for they consist in improvements on the old line. The self-content and indifference of the "monopoly" has been rudely dispelled. Time-tables are to be revised and abbreviated. Let us hope that dinner-tables will suffer some reform also. Perhaps the amelioration may be contagious, and spread even to the Central Pacific, which, being still a monopoly, would not wake up of itself. Perhaps Providence may also lend a helping hand. Perhaps, some happy day, the eating-house at Elko may be struck by lightning! But these are mere day-dreams! *

DENVER, June 21, 1883.

STEEL CASTINGS IN PLACE OF IRON AND STEEL FORGINGS.*

It is well known by those who have the management of steamships, and the responsibility of keeping them in efficient working order, that large forged stern frames and rudder frames, as now made, are seldom absolutely sound. Numbers of cases of these forgings having failed when put to work come under our notice, and afford sufficient evidence of the necessity of some improvement being made; while the mortality of wrought-iron crank-shafts belonging to the mercantile marine of this country is excessive. Now, if these parts of steamships and marine engines can be cast sound, solid, thoroughly homogeneous, and free from internal strain, and at the same time possessing the requisite strength and ductility, it will be a great advantage for engineers and ship-builders, and eventually also for ship-owners, to adopt this material for these purposes.

At present, however, the subject of solid steel castings of these forms is somewhat in its infancy, and it is but natural that much doubt and suspicion should be found to exist in the minds of many who for the first time approach the question, just as, some four or five years ago, great distrust was manifested in many quarters as to the reliability and suitability of mild steel for plates, angles, and rivets for shipbuilding and marine boiler-making. The hesitation in adopting the new material was doubtless strengthened by the many cases of mysterious fractures, and the instances of excessive corrosion brought forward to show the unwisdom of changing from iron to steel; but these doubts no longer exist, and the superiority of mild steel over iron for the principal structural parts of a ship is now freely acknowledged. In proof of this, I may mention that last year there were no less than 73 large steamships built of steel, with a tonnage of about 143,000; that 116 vessels, with a total tonnage of 216,784, were building of steel in January last; and that at the present time, there are more than six times as many marine boilers making in this country of mild steel as there are making of iron.

During the past twelve months, several applications have been made, by various firms, to the society which I have the honor of serving, for its approval of the use, in vessels classed by Lloyd's Register, of steel castings for such purposes as stems, stern-frames, rudders, tiller-quadrants, and other parts of vessels, and also for crank-shafts, levers, link-blocks, and other portions of marine engines, these parts having usually been made of wrought-iron. Before coming to any decision on the matter, the committee of Lloyd's Register decided to fully investigate, first, the physical properties of the material intended to be used, such as its strength to resist various kinds of strain, its ductility, the homogeneity and soundness of casting of such forms as were desired to be used, and also as to whether the processes by which these castings were made and the raw materials employed were such as would be reasonably expected to secure certainty as to the results obtained; and finally, to consider what tests it would be practicable to use to determine the quality of the material after the castings have been made. With this object in view, visits were made to the three firms in this country who proposed making these large steel castings, and the views were elicited of those gentlemen who have had practical experience with these castings, as well as those who have been actively engaged in heavy forgings for shaftings and complicated parts of machinery. Subsequently, also, visits were made to the works of, and consultations held with, the principal steel-makers in France, a country where, up to the present time, much greater attention has been bestowed upon such matters than in our own. Tests were also made, not only upon samples of the material cut out of castings, but also upon castings themselves, and similar tests were conducted upon samples of forged iron and forged steel. The result is, that structures can be made of cast-steel quite as fit for the purpose intended as those usually constructed of wrought-iron, and that they can, at the same time, be made in such a manner as to avoid the uncertainty inevitably associated with large iron forgings, owing to the large number of weldings necessitated in them.

Although there is no doubt that very successful steel castings have been made by each of the three makers referred to as being engaged in this trade, namely, Messrs. Jessop & Sons, of Sheffield, Messrs. Spencer & Sons, of Newburn-on-Tyne, and the Steel Company of Scotland, of Glasgow, it is strange that such diverse opinions and practices prevail at these works, and perhaps equally strange that such opposite opinions are held upon the question of large forgings, both in iron and steel, experience of which has been obtained from the practice of many years.

At the works of Messrs. Jessop, for instance, the opinion is held, and

* Abstract of a paper read by Mr. William Parker, of Lloyd's Register of Shipping, before the British Iron and Steel Institute.

Digitized by Google

the practice is in accordance with this opinion, that, in order to insure a definite composition of the material with the precision which is necessary, and to obtain thorough homogeneity throughout a large casting, it is absolutely necessary to melt the steel in crucibles. The material put into each crucible having a definite composition, it is claimed that the resulting fluid steel remains of identically the same composition; while the opinion is held that, if steel is melted in large masses in a Siemens furnace, although the resulting metal may be sufficiently homogeneous for plate purposes, it is not sufficiently so for many structures where absolute homogeneity and freedom from internal molecular strains are required in every part. At the other works, on the contrary, the opinion is held that homogeneity may be obtained in metal melted in Siemens furnaces. Messrs. Spencer & Sons use both crucibles and open-hearth furnaces to melt their steel, the size of the castings being their only guide in this matter, and they find absolutely no difference as to the material, whichever process is used; while the Steel Company of Scotland uses the open-hearth furnaces for every purpose. Messrs. Jessop and Messrs. Spencer both seem to hold the opinion that the requisite composition of the resulting steel, to insure not only strength and ductility, but also solidity and soundness, can be obtained by careful attention to the materials employed. At the works of the Steel Company of Scotland, however, the process is essentially that known as the Terre-Noire. The metal is melted in an open-hearth Siemens furnace, a bath being formed of a mixture of manganiferous pig-iron and steel scrap by melting these materials together. Successive additions of hot steel scrap are then made, until the bath contains a sufficiently low amount of carbon to give the resulting product the hardness desired. There is then added an amount of an alloy called silicide of manganese, which insures the solidity of the steel and its freedom from blow-holes, the metal being finally tapped into a ladle, and run into molds in the usual manner. Throughout the operation, the greatest care is taken to prevent oxidation of the metal as far as possible. No ore is used, as the company, being a large maker of steel plates, always has available a large quantity of mild steel scrap of definite composition. The plan of using a compound of iron, manganese, and silicon, as is always done at these works in place of the older method of using glazed iron—which is iron and silicon without any manganese—is held to be preferable for the following reason: When glazed iron—or iron and silicon—alone is used, a portion of the silicon is oxidized by the small amount of oxygen which the metal has taken up, forming a silicate which is very difficult of fusion even at a steel-melting heat; consequently, a certain amount of slag is left intimately mixed with the iron, and metal thus made is composed of particles of metal separated from each other by a very thin coating or film of slag. This renders the resulting metal very "short" and brittle, and no amount of subsequent annealing completely rectifies it. On the other hand, when an alloy of silicon, iron, and manganese is used, a compound slag is formed, into the composition of which the manganese enters; this is very fusible at a steel-melting heat, and rapidly rises to the surface of the metal, leaving the metal itself perfectly free from slag.

Whichever process is used for obtaining the molten steel, great difficulties have to be overcome in successfully making castings of any but the simplest forms. The high temperature required in order to give the metal sufficient fluidity necessarily causes the castings to have a large contraction, which not only is a great cause of "piping," since steel castings can not be "fed" like other castings, but, in order to prevent fracture of the casting while in the mold, great judgment is required in making the mold sufficiently fragile to yield under the contraction strain, and at the same time to give it a sufficiently rigid surface, and make it sufficiently strong to withstand the wash and pressure of the metal while it is fluid. The temperature, too, is so high that it is difficult to find a material suitable for facing the molds, refractory enough to withstand the temperature, and at the same time avoiding chemical action on the metal used. When the casting is satisfactorily obtained, great differences of opinion are held as to the necessity for or the utility of annealing. At Messrs. Jessop's, the opinion is held that the careful cooling of the original casting, so as to insure a uniform cooling throughout, is the only means of insuring molecular equilibrium and freedom from internal strain, and that any subsequent heating must necessarily be far from uniform, the outer and thinner portions being first heated, and that this want of uniformity of temperature produces molecular strains in the material, which subsequent cooling, however carefully performed, can not entirely remove. All other steel-makers, however, consider that the cooling which takes place in the mold can not be so uniformly performed as to leave the casting free from molecular strains; while even if this could be done, the rigidity of the mold itself must necessarily create some molecular strains, and they consider that the only way in which these strains can be set at rest is by careful annealing. The annealing process here meant is not a decarburizing one, no chemical change being produced in the material; but it consists of slowly and uniformly raising the temperature of the casting to a bright-red heat, keeping it at that temperature for a length of time, dependent upon the form and dimensions of the casting, and then slowly and uniformly cooling it.

M. Pourcel, of Terre-Noire, attaches great importance, not only to annealing, but also to tempering castings in oil, in order to give them a greater degree of ductility. He contends that the metal in castings, especially those of a complex character with abrupt terminations and changes of form cast in a sand mold, can not be of a uniform nature. In castings comprising various degrees of thickness, the thin sections of metal must cool more rapidly than the thick ones; and besides setting up strains, this varying rate of cooling causes a difference of crystallization in the various parts, and that to such an extent that uniform crystallization and molecular equilibrium in such castings can not be entirely obtained by merely annealing, which is effectual for this purpose in ordinary plain castings. Tempering, or in other words, cooling the castings in oil is, however, very beneficial. The first application entirely transforms the large crystalline grain of the metal into a finer and more homogeneous grain, while each successive repetition still further adds to its homogeneity, tenacity, and ductility. As an illustration of this, I had four specimens cut from a casting made at Terre-Noire, and tested under my own supervision. The first specimen, in the same condition as when cut from the casting, broke with a tensile stress of 32·07 tons per square inch and an elongation of 16 per cent in a length of 5 inches; the next specimen, which was annealed, broke at a stress of 33·7 tons per square inch with an elongation of 17 per cent; the third specimen was annealed and tempered in oil, and broke at a stress of 38·6 tons per square inch, having an elongation of 17 per cent; and the fourth specimen, which was twice tempered in oil, broke with a stress of 41·1 tons per square inch, with an elongation of 15 per cent. The specimens can be seen on the table, and on examination of the fractures it will be observed that the structure of the material is very much closer and finer after each annealing and tempering.

It must be remembered that the molecular strains induced through irregular cooling are not peculiar to steel; they occur in all castings; and although in brass and gun-metal castings the ductility of the metal is sufficiently great in comparison with the contraction in cooling to warrant these strains being practically ignored, yet in cast-iron the want of ductility is such that complicated castings are probably never made without being "drawn," while it is absolutely impossible to cast many forms in iron; and even with all the ingenuity obtained from long experience, it is not by any means uncommon for large cylinders and other marine engine castings to be actually fractured in parts before being taken out of the mold. Even in forgings, these strains are sufficiently severe to cause actual rupture in cooling; for instance, the cavities or so-called flaws often found in the center of large couplings forged with shafts are due to the fact that the outer portion of the coupling first cools and becomes comparatively unyielding; and in the subsequent cooling, the contraction of the inner portion being prevented from taking place radially by the strong cold outer portion, draws the metal asunder at or near the center.

THE CONSUMPTION OF CHEMICALS BY THE ALIZARINE INDUSTRY.

There is a strong movement on foot in England to manufacture the alizarine required by the dyers and calico-printers of England and Scotland. Mr. Joan Levinstein, in a paper before the Society of Chemical Industry, estimates the consumption of all countries at about 9000 tons per annum. For the production of 9000 tons of artificial 20 per cent alizarine, there are required somewhere about 3000 tons of from 55 to 60 per cent anthracene; from 3000 to 4000 tons of bichromate of potash (in this estimate there is no allowance made for the regeneration of the chromates); 18,800 tons of rectified sulphuric acid, or correspondingly less when muriatic acid is used for precipitating the alizarine; from 2000 to 3000 tons of from 45 to 50 per cent anhydrous fuming sulphuric acid; 10,000 tons of 70 per cent white caustic soda (this includes the necessary quantity of carbonate); and from 450 to 500 tons of chlorate of potash.

PEROXIDE OF HYDROGEN AND ITS INDUSTRIAL APPLICATION.

Oxygenated water, a common name for peroxide of hydrogen, has attracted within the last few years a good deal of attention, and it has been successfully employed for several useful purposes, such as the bleaching of tussah silks, the bleaching of ostrich feathers, etc., and is recommended for other applications. However, until some time ago, there was always a difficulty in getting the product in sufficient quantity and at such a price and strength that it could be used on an industrial scale. This difficulty seems to have been now removed, or rather to be on the point of being removed, by the attention which is paid by several manufacturers to the preparation of this useful product. It is stated that Mr. P. Ebell, of Pfungstadt, near Darmstadt, has succeeded in preparing economically a product pure, stable, and of constant strength, and capable of being easily transported to long distances, and to be kept for years without losing its bleaching properties. If, however, the temperature does not go above 30° C., it is kept in a dark place. Among other applications of this product, that of the decoloration of animal fibers is the most important, as it does not contain some of the disadvantages of other bleaching agents. For wool and silk, it is advisable, before bleaching, to cleanse the materials thoroughly, so as to eliminate all the greasy substances and impurities. For this purpose, Mr. Ebell recommends a bath in a solution of five parts carbonate of ammonia to 100 of water, this bath being followed by a soaping and thorough washing with water. The bleaching itself is performed either by immersing the materials in the solution of oxygenated water, and left there at a temperature of from 20° to 30° C., until the decoloration is complete, or the materials are impregnated, when they were wrung out and exposed in a room heated to about 20° C., where they are left to dry. In order to insure an even bleaching, it is well to agitate the materials by means of a mechanical arrangement. Hair is bleached by immersion in oxygenated water for a couple of days, the material having been previously cleansed by means of five per cent carbonate of ammonia and well washed with water. For bleaching ostrich feathers, almost the only decolorizing agent used nowadays is the peroxide of hydrogen. The feathers are cleaned first in a bath at 20° C., with from two to three per cent of carbonate of ammonia, for about twelve hours, by moving from time to time; they are then removed and washed, first with tepid soap-water, and afterward rinsed with fresh water. The bleaching bath of hydrogen peroxide is rendered slightly alkaline, and the feathers are immersed for two days, then rinsed with water, which must not contain any lime, and then dried at the ordinary temperature by a current of air, otherwise with still air the feathers would take a horny feeling and appearance. Ivory, bone, and wax can also be bleached by means of the peroxide of hydrogen. While Germany is starting the manufacture of this bleaching agent on a fairly large scale, English chemists do not remain idle in this field, and, in fact, attempts are now making in the English alkali district to produce on a very extended scale not the hydrogen peroxide but a product capable of giving the same results, namely, calcium peroxide. Mr. Ludwig Mond has taken out patents for commercially producing calcium peroxide. He proposes to first produce peroxide of barium, which is decomposed under pressure by means of carbonic acid and water into barium carbonate and hydrogen peroxide. The carbonate of barium thus formed, after separation from the liquor, is used again for the production of the peroxide of hydrogen, while, by adding milk of lime to the liquor, hydrated peroxide of calcium is precipitated, and forms the commercial product. This material, if brought on the market at a low price, will no doubt find many very useful and extended applications in the industrial arts, and especially for bleaching purposes.

tributary of Green River. It was a regret to me, in choosing this route, that I should miss the familiar and beloved scenery of Weber and Echo cañons—the only part of the Union Pacific road which tempts one to look out of the car-window, unless one may be tempted by the boundless monotony of the plains or the chance of a prairie-dog. Great was my satisfaction, therefore, to find that this part of the new road, parallel with the Union Pacific, but a hundred miles farther south, traverses the same belt of rocks, and exhibits them in forms not less picturesque. Castle Cañon, on the South Fork of the Price, is the equivalent of Echo Cañon, and its equal or superior in every thing except color. The brilliant red of the Echo cliffs is wanting. The towers and walls of Castle Cañon are yellowish-gray. But their forms are incomparably various and grotesque—in some instances sublime. The valley of Green River at this point is a cheerless sage-brush desert, as it is farther north. To be sure, this uninviting stream, a couple of hundred miles farther south, having united with the Grand, and formed the Rio Colorado, does indeed, by dint of burrowing deeper and deeper into the sunless chasms, become at last sublime. But here it gives no hint of its future somber glory. I remained awake till we had crossed Green River, to make sure that no striking scenery should be missed by sleep. But I got nothing for my pains except the moonlight on the muddy water; and next time, I shall go to bed comfortably, proving to the conductor that I am a veteran and not a tender-foot.

In the morning, we breakfasted at Cimarron, having in the interval passed the foot-hills of the Roan Mountains, crossed the Grand, and ascended for some distance the Gunnison, a tributary of the Grand, the Uncompahgre, a tributary of the Gunnison, and finally a branch, flowing westward, of the Uncompahgre. A high divide at the head of the latter was laboriously surmounted; and then, one of our two engines shooting ahead and piloting us, we slid speedily down to Cimarron. It is in such descents that the unaccustomed traveler usually feels alarmed. But the experience of the Rio Grande Railroad people is, that derailment is likely to occur on up-grades, and almost never in going down.

From this point, comparison with the Union Pacific line in the matter of scenery ceases. As every body knows, that road crosses the Rocky Mountains proper in a pass so wide and of such gradual ascent that the high summits are quite out of sight. If it were not for the monument to the AMESES, there would be nothing to mark the highest point. For all the wonderful scenery on the Rio Grande road, between Cimarron and Pueblo, the Union Pacific in the same longitudes has nothing to show. From an artistic stand-point, one road has crossed the ranges at the most tame and uninteresting point that could be found, and the other at the most picturesque.

At Cimarron, the road again strikes the Gunnison, and plunges into the famous Black Cañon. In length, variety, and certain elements of beauty, such as forest-ravines and waterfalls, this cañon surpasses the Royal Gorge of the Arkansas. There is, however, one spot in the latter (I mean, of course, the point where the turbulent river fills the whole space between walls 2800 feet high, and the railroad is hung over it) which is superior in desolate, overwhelming grandeur to any thing on the Gunnison. Take them all in all, it is difficult to say which is the finer. I have usually found the opinion of travelers to favor the Gunnison Cañon. But why need the question be solved at all? This one matchless journey comprises them both; and he who was overwhelmed in the morning by the one, holds his breath in the afternoon before the mighty precipices of the other. To excuse myself from even hinting such folly as a comparison of scenery, I will merely remark that these two cañons are more capable of a comparison than different scenes usually are; for they belong to the same type—deep cuts in crystalline rocks.

Between them come the Marshall Pass (nearly 11,000 feet above sea-level) over the continental divide, and the Poncha Pass, over the Sangue di Cristo range. This range contains Harvard, Yale, Princeton, Elbert, Massive (the peak opposite Leadville), and other summits exceeding the altitude of 14,000 feet. To the east of it is the valley of the Arkansas, into which and down which we pass, and so through the Royal Gorge to Cañon City and Pueblo, where we arrive before dark on the day after leaving Salt Lake.

Salt Lake, the Jordan Valley, Utah Lake, the Wahsatch, Castle Cañon, the Black Cañon of the Gunnison, Marshall Pass, Poncha Pass, the Arkansas Valley, the Royal Gorge—what a catalogue for so brief a journey! No wonder every body who has made it is "wild about it." If enthusiastic urgency of recommendation from every passenger has any influence (and I know it has a great deal), this road will continue to be, as it is at present, crowded with tourists. It furnishes a delightful route for those who wish on the overland journey to see Denver (as who does not?) and to visit Colorado Springs and Manitou. All this can be done *en route*, without retracing the steps.

I ought to add that a minor but highly important and agreeable surprise of this trip was the safety and comfort of it. The road-bed is excellent, and laid with steel throughout. The Pullman narrow-gauge sleepers are pretty and comfortable. The officers and servants of the company are extraordinarily attentive—a case of new brooms, perhaps: if so, may they never grow old! And finally, the eating-stations and the meals served in them are better than those on the Union Pacific, and incomparably better than those on the Central Pacific. The Denver & Rio Grande managers have pursued an admirable policy in this particular. They have erected handsome buildings for their eating-stations, and let them rent free to caterers, on the sole condition of excellence in housekeeping, purveying, cooking, and service. Failure in this respect involves summary forfeiture of lease. And finally, they have appointed a competent inspector to have charge of this particular department.

These features of management, coupled with the unique natural attractions of the road, will make it really a dangerous rival to the Union Pacific, so far as through passenger travel is concerned, at least. Already, there are signs of a bitter competition—so far, very welcome signs indeed; for they consist in improvements on the old line. The self-content and indifference of the "monopoly" has been rudely dispelled. Time-tables are to be revised and abbreviated. Let us hope that dinner-tables will suffer some reform also. Perhaps the amelioration may be contagious, and spread even to the Central Pacific, which, being still a monopoly, would not wake up of itself. Perhaps Providence may also lend a helping hand. Perhaps, some happy day, the eating-house at Elko may be struck by lightning! But these are mere day-dreams! *

DENVER, June 21, 1883.

STEEL CASTINGS IN PLACE OF IRON AND STEEL FORGINGS.*

It is well known by those who have the management of steamships, and the responsibility of keeping them in efficient working order, that large forged stern frames and rudder frames, as now made, are seldom absolutely sound. Numbers of cases of these forgings having failed when put to work come under our notice, and afford sufficient evidence of the necessity of some improvement being made; while the mortality of wrought-iron crank-shafts belonging to the mercantile marine of this country is excessive. Now, if these parts of steamships and marine engines can be cast sound, solid, thoroughly homogeneous, and free from internal strain, and at the same time possessing the requisite strength and ductility, it will be a great advantage for engineers and ship-builders, and eventually also for ship-owners, to adopt this material for these purposes.

At present, however, the subject of solid steel castings of these forms is somewhat in its infancy, and it is but natural that much doubt and suspicion should be found to exist in the minds of many who for the first time approach the question, just as, some four or five years ago, great distrust was manifested in many quarters as to the reliability and suitability of mild steel for plates, angles, and rivets for shipbuilding and marine boiler-making. The hesitation in adopting the new material was doubtless strengthened by the many cases of mysterious fractures, and the instances of excessive corrosion brought forward to show the unwisdom of changing from iron to steel; but these doubts no longer exist, and the superiority of mild steel over iron for the principal structural parts of a ship is now freely acknowledged. In proof of this, I may mention that last year there were no less than 73 large steamships built of steel, with a tonnage of about 143,000; that 116 vessels, with a total tonnage of 216,784, were building of steel in January last; and that at the present time, there are more than six times as many marine boilers making in this country of mild steel as there are making of iron.

During the past twelve months, several applications have been made, by various firms, to the society which I have the honor of serving, for its approval of the use, in vessels classed by Lloyd's Register, of steel castings for such purposes as stems, stern-frames, rudders, tiller-quadrants, and other parts of vessels, and also for crank-shafts, levers, link-blocks, and other portions of marine engines, these parts having usually been made of wrought-iron. Before coming to any decision on the matter, the committee of Lloyd's Register decided to fully investigate, first, the physical properties of the material intended to be used, such as its strength to resist various kinds of strain, its ductility, the homogeneity and soundness of casting of such forms as were desired to be used, and also as to whether the processes by which these castings were made and the raw materials employed were such as would be reasonably expected to secure certainty as to the results obtained; and finally, to consider what tests it would be practicable to use to determine the quality of the material after the castings have been made. With this object in view, visits were made to the three firms in this country who proposed making these large steel castings, and the views were elicited of those gentlemen who have had practical experience with these castings, as well as those who have been actively engaged in heavy forgings for shaftings and complicated parts of machinery. Subsequently, also, visits were made to the works of, and consultations held with, the principal steel-makers in France, a country where, up to the present time, much greater attention has been bestowed upon such matters than in our own. Tests were also made, not only upon samples of the material cut out of castings, but also upon castings themselves, and similar tests were conducted upon samples of forged iron and forged steel. The result is, that structures can be made of cast-steel quite as fit for the purpose intended as those usually constructed of wrought-iron, and that they can, at the same time, be made in such a manner as to avoid the uncertainty inevitably associated with large iron forgings, owing to the large number of weldings necessitated in them.

Although there is no doubt that very successful steel castings have been made by each of the three makers referred to as being engaged in this trade, namely, Messrs. Jessop & Sons, of Sheffield, Messrs. Spencer & Sons, of Newburn-on-Tyne, and the Steel Company of Scotland, of Glasgow, it is strange that such diverse opinions and practices prevail at these works, and perhaps equally strange that such opposite opinions are held upon the question of large forgings, both in iron and steel, experience of which has been obtained from the practice of many years.

At the works of Messrs. Jessop, for instance, the opinion is held, and

* Abstract of a paper read by Mr. William Parker, of Lloyd's Register of Shipping, before the British Iron and Steel Institute.

the practice is in accordance with this opinion, that, in order to insure a definite composition of the material with the precision which is necessary, and to obtain thorough homogeneity throughout a large casting, it is absolutely necessary to melt the steel in crucibles. The material put into each crucible having a definite composition, it is claimed that the resulting fluid steel remains of identically the same composition; while the opinion is held that, if steel is melted in large masses in a Siemens furnace, although the resulting metal may be sufficiently homogeneous for plate purposes, it is not sufficiently so for many structures where absolute homogeneity and freedom from internal molecular strains are required in every part. At the other works, on the contrary, the opinion is held that homogeneity may be obtained in metal melted in Siemens furnaces. Messrs. Spencer & Sons use both crucibles and open-hearth furnaces to melt their steel, the size of the castings being their only guide in this matter, and they find absolutely no difference as to the material, whichever process is used; while the Steel Company of Scotland uses the open-hearth furnaces for every purpose. Messrs. Jessop and Messrs. Spencer both seem to hold the opinion that the requisite composition of the resulting steel, to insure not only strength and ductility, but also solidity and soundness, can be obtained by careful attention to the materials employed. At the works of the Steel Company of Scotland, however, the process is essentially that known as the Terre-Noire. The metal is melted in an open-hearth Siemens furnace, a bath being formed of a mixture of manganiferous pig-iron and steel scrap by melting these materials together. Successive additions of hot steel scrap are then made, until the bath contains a sufficiently low amount of carbon to give the resulting product the hardness desired. There is then added an amount of an alloy called silicide of manganese, which insures the solidity of the steel and its freedom from blow-holes, the metal being finally tapped into a ladle, and run into molds in the usual manner. Throughout the operation, the greatest care is taken to prevent oxidation of the metal as far as possible. No ore is used, as the company, being a large maker of steel plates, always has available a large quantity of mild steel scrap of definite composition. The plan of using a compound of iron, manganese, and silicon, as is always done at these works in place of the older method of using glazed iron—which is iron and silicon without any manganese—is held to be preferable for the following reason: When glazed iron—or iron and silicon—alone is used, a portion of the silicon is oxidized by the small amount of oxygen which the metal has taken up, forming a silicate which is very difficult of fusion even at a steel-melting heat; consequently, a certain amount of slag is left intimately mixed with the iron, and metal thus made is composed of particles of metal separated from each other by a very thin coating or film of slag. This renders the resulting metal very "short" and brittle, and no amount of subsequent annealing completely rectifies it. On the other hand, when an alloy of silicon, iron, and manganese is used, a compound slag is formed, into the composition of which the manganese enters; this is very fusible at a steel-melting heat, and rapidly rises to the surface of the metal, leaving the metal itself perfectly free from slag.

Whichever process is used for obtaining the molten steel, great difficulties have to be overcome in successfully making castings of any but the simplest forms. The high temperature required in order to give the metal sufficient fluidity necessarily causes the castings to have a large contraction, which not only is a great cause of "piping," since steel castings can not be "fed" like other castings, but, in order to prevent fracture of the casting while in the mold, great judgment is required in making the mold sufficiently fragile to yield under the contraction strain, and at the same time to give it a sufficiently rigid surface, and make it sufficiently strong to withstand the wash and pressure of the metal while it is fluid. The temperature, too, is so high that it is difficult to find a material suitable for facing the molds, refractory enough to withstand the temperature, and at the same time avoiding chemical action on the metal used. When the casting is satisfactorily obtained, great differences of opinion are held as to the necessity for or the utility of annealing. At Messrs. Jessop's, the opinion is held that the careful cooling of the original casting, so as to insure a uniform cooling throughout, is the only means of insuring molecular equilibrium and freedom from internal strain, and that any subsequent heating must necessarily be far from uniform, the outer and thinner portions being first heated, and that this want of uniformity of temperature produces molecular strains in the material, which subsequent cooling, however carefully performed, can not entirely remove. All other steel-makers, however, consider that the cooling which takes place in the mold can not be so uniformly performed as to leave the casting free from molecular strains; while even if this could be done, the rigidity of the mold itself must necessarily create some molecular strains, and they consider that the only way in which these strains can be set at rest is by careful annealing. The annealing process here meant is not a decarburizing one, no chemical change being produced in the material; but it consists of slowly and uniformly raising the temperature of the casting to a bright-red heat, keeping it at that temperature for a length of time, dependent upon the form and dimensions of the casting, and then slowly and uniformly cooling it.

M. Pourcel, of Terre-Noire, attaches great importance, not only to annealing, but also to tempering castings in oil, in order to give them a greater degree of ductility. He contends that the metal in castings, especially those of a complex character with abrupt terminations and changes of form cast in a sand mold, can not be of a uniform nature. In castings comprising various degrees of thickness, the thin sections of metal must cool more rapidly than the thick ones; and besides setting up strains, this varying rate of cooling causes a difference of crystallization in the various parts, and that to such an extent that uniform crystallization and molecular equilibrium in such castings can not be entirely obtained by merely annealing, which is effectual for this purpose in ordinary plain castings. Tempering, or in other words, cooling the castings in oil is, however, very beneficial. The first application entirely transforms the large crystalline grain of the metal into a finer and more homogeneous grain, while each successive repetition still further adds to its homogeneity, tenacity, and ductility. As an illustration of this, I had four specimens cut from a casting made at Terre-Noire, and tested under my own supervision. The first specimen, in the same condition as when cut from the casting, broke with a tensile stress of 32·07 tons per square inch and an elongation of 16 per cent in a length of 5 inches; the next specimen, which was annealed, broke at a stress of 33·7 tons per square inch with an elongation of 17 per cent; the third specimen was annealed and tempered in oil, and broke at a stress of 38·6 tons per square inch, having an elongation of 17 per cent; and the fourth specimen, which was twice tempered in oil, broke with a stress of 41·1 tons per square inch, with an elongation of 15 per cent. The specimens can be seen on the table, and on examination of the fractures it will be observed that the structure of the material is very much closer and finer after each annealing and tempering.

It must be remembered that the molecular strains induced through irregular cooling are not peculiar to steel; they occur in all castings; and although in brass and gun-metal castings the ductility of the metal is sufficiently great in comparison with the contraction in cooling to warrant these strains being practically ignored, yet in cast-iron the want of ductility is such that complicated castings are probably never made without being "drawn," while it is absolutely impossible to cast many forms in iron; and even with all the ingenuity obtained from long experience, it is not by any means uncommon for large cylinders and other marine engine castings to be actually fractured in parts before being taken out of the mold. Even in forgings, these strains are sufficiently severe to cause actual rupture in cooling; for instance, the cavities or so-called flaws often found in the center of large couplings forged with shafts are due to the fact that the outer portion of the coupling first cools and becomes comparatively unyielding; and in the subsequent cooling, the contraction of the inner portion being prevented from taking place radially by the strong cold outer portion, draws the metal asunder at or near the center.

THE CONSUMPTION OF CHEMICALS BY THE ALIZARINE INDUSTRY.

There is a strong movement on foot in England to manufacture the alizarine required by the dyers and calico-printers of England and Scotland. Mr. Joan Levinstein, in a paper before the Society of Chemical Industry, estimates the consumption of all countries at about 9000 tons per annum. For the production of 9000 tons of artificial 20 per cent alizarine, there are required somewhere about 3000 tons of from 55 to 60 per cent anthracene; from 3000 to 4000 tons of bichromate of potash (in this estimate there is no allowance made for the regeneration of the chromates); 18,800 tons of rectified sulphuric acid, or correspondingly less when muriatic acid is used for precipitating the alizarine; from 2000 to 3000 tons of from 45 to 50 per cent anhydrous fuming sulphuric acid; 10,000 tons of 70 per cent white caustic soda (this includes the necessary quantity of carbonate); and from 450 to 500 tons of chlorate of potash.

PEROXIDE OF HYDROGEN AND ITS INDUSTRIAL APPLICATION.

Oxygenated water, a common name for peroxide of hydrogen, has attracted within the last few years a good deal of attention, and it has been successfully employed for several useful purposes, such as the bleaching of tussah silks, the bleaching of ostrich feathers, etc., and is recommended for other applications. However, until some time ago, there was always a difficulty in getting the product in sufficient quantity and at such a price and strength that it could be used on an industrial scale. This difficulty seems to have been now removed, or rather to be on the point of being removed, by the attention which is paid by several manufacturers to the preparation of this useful product. It is stated that Mr. P. Ebell, of Pfungstadt, near Darmstadt, has succeeded in preparing economically a product pure, stable, and of constant strength, and capable of being easily transported to long distances, and to be kept for years without losing its bleaching properties. If, however, the temperature does not go above 30° C., it is kept in a dark place. Among other applications of this product, that of the decoloration of animal fibers is the most important, as it does not contain some of the disadvantages of other bleaching agents. For wool and silk, it is advisable, before bleaching, to cleanse the materials thoroughly, so as to eliminate all the greasy substances and impurities. For this purpose, Mr. Ebell recommends a bath in a solution of five parts carbonate of ammonia to 100 of water, this bath being followed by a soaping and thorough washing with water. The bleaching itself is performed either by immersing the materials in the solution of oxygenated water, and left there at a temperature of from 20° to 30° C., until the decoloration is complete, or the materials are impregnated, when they were wrung out and exposed in a room heated to about 20° C., where they are left to dry. In order to insure an even bleaching, it is well to agitate the materials by means of a mechanical arrangement. Hair is bleached by immersion in oxygenated water for a couple of days, the material having been previously cleansed by means of five per cent carbonate of ammonia and well washed with water. For bleaching ostrich feathers, almost the only decolorizing agent used nowadays is the peroxide of hydrogen. The feathers are cleaned first in a bath at 20° C., with from two to three per cent of carbonate of ammonia, for about twelve hours, by moving from time to time; they are then removed and washed, first with tepid soap-water, and afterward rinsed with fresh water. The bleaching bath of hydrogen peroxide is rendered slightly alkaline, and the feathers are immersed for two days, then rinsed with water, which must not contain any lime, and then dried at the ordinary temperature by a current of air, otherwise with still air the feathers would take a horny feeling and appearance. Ivory, bone, and wax can also be bleached by means of the peroxide of hydrogen. While Germany is starting the manufacture of this bleaching agent on a fairly large scale, English chemists do not remain idle in this field, and, in fact, attempts are now making in the English alkali district to produce on a very extended scale not the hydrogen peroxide but a product capable of giving the same results, namely, calcium peroxide. Mr. Ludwig Mond has taken out patents for commercially producing calcium peroxide. He proposes to first produce peroxide of barium, which is decomposed under pressure by means of carbonic acid and water into barium carbonate and hydrogen peroxide. The carbonate of barium thus formed, after separation from the liquor, is used again for the production of the peroxide of hydrogen, while, by adding milk of lime to the liquor, hydrated peroxide of calcium is precipitated, and forms the commercial product. This material, if brought on the market at a low price, will no doubt find many very useful and extended applications in the industrial arts, and especially for bleaching purposes.

BESSEMERIZING COPPER MATTE.

The following letter, addressed by Dr. Percy to Dr. Raymond, has been delayed in publication by the absence of the latter in the West:

TO THE EDITOR:

SIR: In the last number of the ENGINEERING AND MINING JOURNAL which I have received (dated May 5th, 1883), I have read the correspondence concerning what is termed "Bessemerizing Copper Matte." In the first letter, it is stated that the first attempts were made in Russia in 1867. I send you by this post the specification of a patent for this process granted in 1856 to my old friend, Mr. Keates, one of our most experienced copper-smelters. It is remarkable how much seems either to be forgotten or ignored by some modern inventors.

I remain, very truly yours, JOHN PERCY.

HOUSE OF COMMONS, LONDON, May 18, 1883.

The patent of William Keates, of Liverpool, to which Dr. John Percy, the distinguished metallurgist, refers, is dated September 4th, 1856; and the invention is described substantially as follows:

The ore or other cupriferous material is first smelted to a regulus, and then introduced into a special furnace, in which, during or after fusion, currents of air, artifically heated if desired, are either forced at high pressure through the molten mass, or directed upon its surface.

The apparatus shown in the appended drawings is a reverberatory furnace, with four tuyeres at the corners, and two doors (besides the door of the fire-chamber), one at the end opposite the fire, for the withdrawal of slags, and the other on one side for charging. On the other side, not exactly opposite the charging-door, is the tap-hole, through which the coarse copper is run out into sand-beds. The patentee, with the usual comprehensiveness of his class, claims any other form of furnace or means of introducing the desulphurizing currents of air. On the details of the process, the following information only is vouchsafed:

"The general *modus operandi* is as follows, but may be varied to suit the convenience of special circumstances: The regulus or matte being introduced into the furnace in any of the usual modes, the apertures are closed and the fire urged until the regulus has nearly attained the fusing-point; the blast is then turned on and the heat of the furnace increased to effect a perfect fusion while subject to the operation of the blast. This process is continued (occasionally removing the slag or scoria formed during the operation) until the whole of the copper becomes metallic, when it is tapped out of the furnace into sand or other molds prepared for its reception. If found more convenient for the purposes of the smelting-works or manufactory, the contents of the furnace may be tapped out when only partially desulphurized, and again submitted to this process, or refined in the usual manner."

As to the tuyeres, Mr. Keates declares that he uses, where iron would not stand, fire-clay or "composition," either in cylindrical tubes, or square or octagonal blocks traversed by a cylindrical cavity, the latter being glazed, and the tubes or blocks joined with socket-joints and luted with fine fire-clay. These are built into the walls and under the sole of the furnace, thus forming an integral part of the structure. *

A REPLY TO MR. C. A. STETEFELDT.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: My old friend, Mr. C. A. Stetefeldt, of New York City, has seen fit to criticise, in the issue of this paper of June 16th, 1883, a report of mine, made some time ago, to the owners of the Mount Cory mine in Nevada. He does not limit himself to professional criticism, as he properly should, but indulges in personalities. He charges that I never built or ran a Stetefeldt furnace, and consequently, in his opinion, I do not know what a Stetefeldt furnace is, nor what it can do. My answer to this charge is, that Mr. Stetefeldt is forgetful of the fact, that at least one, and often several Stetefeldt furnaces have been in constant operation at one or more places on this coast for a long time; that they were open to inspection and study, if indeed any study were required to understand his furnace; that its results are matters of record; that various publications discuss the Stetefeldt furnace; and that last, but not least, Mr. Stetefeldt himself has done all he could, true to the nature of a patentee, to disseminate knowledge of the Stetefeldt furnace and what it can do, throughout this country at least, both by pamphlets and verbal discussions. I suppose this disposes of Mr. Stetefeldt's charge as to my ignorance of a Stetefeldt furnace. I will add, however, as a parting conclusion, that if an extensive experience in running the furnace is required in order to understand it, then the furnace is less recommendable than I supposed it was, and Mr. Stetefeldt himself can not be the best Stetefeldt furnace man.

In the same ungenerous mood, he charges me with limited experience in amalgamation, because I have had charge of a tailings mill in Dayton, Nevada. Generally, amalgamation consists in a few simple operations, and when it ceases to be that, when the "chemicals," from bluestone down to snuff, fail to produce satisfactory results, the ore is pronounced to be of a refractory character. If there were any particular difficulty in amalgamation to be overcome, and hence more skill were required in one case than in another, naturally the tailings amalgamator, so much despised by Mr. Stetefeldt, would be the more skillful amalgamator; for if successful, he extracts that which the ore amalgamator could not take out. Now, if raw amalgamation, to which I have referred so far, is not much of a trick, amalgamation of roasted ore is still less so, for obvious reasons. The tailings mill I did run at Dayton was a success; it treated 300 tons of tailings per day, and its owner grew rich on it. Besides all this, amalgamating mills have been numerous for a long time on this coast; they were always open to inspection, and their results matters of record.

Mr. Stetefeldt charges me with having formulated general laws for metallurgists to be guided by in the future. This is not so, although, I must say, it is never too late for any one to learn. Whatever I did say in that report was simply intended for a private party, and was said of a particular kind of ore.

Mr. Stetefeldt seems to be ignorant of various facts concerning this report of mine, and labors under a misconception of what I say in it. To enlighten him, if I can, I beg to submit the following statement and reports, to wit:

Some time ago, I was employed to determine the most feasible plan for working Mount Cory ore. This ore consists of quartz as gangue, the silver-bearing minerals being galena, zinc-blende, native silver, fahlore, copper and iron sulphides; the gangue in the ore amounting to from 85 to 95 per cent. Crushing and chloridizing, roasting, with subsequent amalgamation or leaching, were what I determined would be the most favorable for working the ore. Stamps have heretofore been almost the universal means for crushing under similar circumstances, roasting and amalgamation the subsequent treatment. Since there were opportunities to practically test the ore by either stamps or Krom rolls, the Stetefeldt furnace or cylinder furnaces, amalgamation or leaching, we availed ourselves of these opportunities. In all cases, the tests were not made under my supervision alone, but also under the supervision of the respective superintendents and foremen of the mills, all gentlemen whom I have the pleasure of knowing as efficient officers, and all of whom have the experience so highly valued for once by Mr. Stetefeldt. When the test was made in the Northern Belle mill, I was not even present. Mr. Belding, who conducted the test, has, however, all the experience Mr. Stetefeldt possibly can desire him to have. The test in the Geddes & Bertrand mill was conducted in the presence of Mr. Eckart, the mechanical engineer of the Mount Cory mill, the superintendent and foreman of the mill, and myself. Below will be found the results as obtained in each mill. My conclusions were drawn from these results, and I should be pleased to know what kind of a plant Mr. Stetefeldt would have recommended if he had been in my position. The ore used for the tests was practically of the same kind and character. It is true, Mr. Belding has used only one ton of Mount Cory ore to make his test with, although I had recommended to treat ten tons at least; yet Mr. Belding has such extensive experience with the Stetefeldt furnace and pan-work that, considering Mr. Stetefeldt's valuation of experience, he will hardly find fault with Mr. Belding's proceeding. The reports speak for themselves and are as follows:

STAMPS, STETEFELDT FURNACE, AND AMALGAMATION.

OFFICE OF NORTHERN BELLE MILL AND MINING CO.,
BELLEVILLE, NEV., March 21, 1883.

A. G. MCKENZIE, *Sup't Mount Cory Mining Co.:*

DEAR SIR: Two thousand and eighty pounds of your second-class ore were received in due time, crushed, roasted, and amalgamated, with the following results:

The crushing was at the rate of 44 tons per twenty-four hours, with 20 stamps of 1000 pounds each, dropping 8 inches, 96 times per minute.

The value per ton was $43.79. Loss in roasting, 5 per cent of weight, and 9 per cent of value. Loss in tailings, 14 per cent of value, making a total loss (after deducting 19 per cent—estimated mechanical loss between furnace and tailings) of 24 per cent in value, or a yield of 76 per cent. Fractions have been omitted in my calculations.

This I consider good work for the grade and character of the ore. More experience would, without doubt, improve this materially.

I am satisfied that the Stetefeldt furnace will handle such ore successfully, while the cost of reduction ought not to exceed $10 per ton, with wood at $5 per cord and salt at $20 per ton.

The fineness of bullion from this test will be forwarded by next mail; the amalgam appears to be of fair grade. Yours truly,

WILLIAM F. BELDING.

BELLEVILLE, NEVADA, March 22, 1883.

A. G. MCKENZIE, *Sup't Mount Cory Mining Co., Hawthorne, Nevada:*

DEAR SIR: The fineness of bullion produced from your ore is 786, the base being copper. Yours truly, WILLIAM F. BELDING.

WORKING TEST AT BERTRAND MILL.

G. R. WELLS: SAN FRANCISCO, April 27, 1883.

DEAR SIR: Below please find results of the recent working of three charges of Mount Cory ore at the Bertrand mill, Geddes, Nev., and my opinion, to wit:

ROLLS.

Lot 1.—18,200 pounds—9 1/10 tons of Mount Cory ore—and 1820 pounds of salt were crushed by a crusher and two sets of rolls through a No. 20 screen, in 4 hours and 17 minutes. The resulting pulp was a rather coarse material, but it roasted pretty well, as was subsequently ascertained. Thus the crushing capacity for Mount Cory ore of said mill is nearly 50 tons of ore and 5 tons of salt per twenty-four hours, all crushed through a No. 20 screen.

Lot 2.—7201 pounds of Mount Cory ore and 1080 pounds of salt were crushed by the same machinery through a No. 30 screen, in 3 hours 52 minutes. Thus the crushing capacity of said mill for Mount Cory ore and 15 per cent salt, for the time being, and crushing through a No. 30 screen, was at the rate of 22 1/2 tons of ore and 2 1/4 tons of salt.

The machinery consisted of one crusher, two pairs of rolls, elevator, screens, etc. The crusher and first pair of rolls (roughing rolls) were out of order, being in a worn-out condition; the second pair of rolls (finishing rolls) were in first-class condition, having been provided with new steel rings only three weeks ago. Under the circumstances, said finishing rolls had to do most of the work, I should say about two thirds of it, while the crusher and roughing rolls together, perhaps, performed one third. Taking this assumption for a fact, one pair of rolls will crush say 15 tons through a No. 30 screen in twenty-four hours, or two sets 30 tons, three sets 45 tons, etc. The latter pulp (crushed through a 30 screen) was still much coarser than a dry stamp battery will crush through a like screen, owing to the different manner of screening the pulp in each case compared with the other.

If, then, a certain number of stamps crush nearly 45 tons of Mount Cory ore through a No. 30 screen, as was done at the Northern Belle mill said number of stamps do more than three sets of rolls would; that is to say, said number of stamps would be preferable to three pairs of rolls when fine pulp is required, and *vice versa* when not. For roasting in a Stetefeldt furnace and subsequent amalgamation, or amalgamation in any case, finely-divided pulp is required, while for purposes of leaching, a coarse material is just as good, and even preferable, for which reasons stamps, Stetefeldt furnaces, and amalgamating pans should go together, and rolls, cylindrical roasting-furnaces, and leaching tubs also.

ROASTING-FURNACES.

The roasting-furnaces, four in number, are of what is called the Brückner style, simplified. They have a capacity of about 12 1/2 tons of Mount

Cory ore, will need about 5 per cent of salt, using 2½ cords of nut-pine wood each. That is to say, the four furnaces can roast about 50 tons in twenty-four hours with 10 cords of wood, requiring the attention of 8 men in 12-hour shifts in the twenty-four hours. There are three roasters on each shift, 6 per twenty-four hours, and 2 dustmen during the day shift. A Stetefeldt furnace of the same capacity these four furnaces possess will use about 5 cords of wood, 5 per cent salt, and 3 men in 8-hour shifts in the twenty-four hours, the Stetefeldt furnace not requiring any power to drive it except his elevator and screen, which is very little compared with the power to drive these four furnaces, each of which requires from 4 to 6 horse-power all the time. All these facts speak in favor of the Stetefeldt furnace. But, at the same time, the Stetefeldt furnace requires finely-divided pulp, and to obtain it stamps are necessary, which stamps are certainly more expensive in every way than rolls, and, after roasting such fine pulp, amalgamation must follow, which again is in every respect more expensive than leaching.

LIXIVIATION.

There are 24 leaching-tubs at the Bertrand mill, and since Mount Cory ore will leach in about forty-eight hours in charges of from 4½ to 5½ tons, said mill could leach about 50 tons in twenty-four hours. We leached three different charges of Mount Cory ore. The first was finished in 60 hours, the second in 40 hours, the third in 48 hours. The tailings showed respectively 3·63 ounces, 4·80 ounces, and 2·62 ounces per ton. I can hardly believe that amalgamation will give lower tailings, nor that the Stetefeldt furnace will lose less silver in roasting. A comparison with Mr. Belding's reports will show the differences between lixiviation and amalgamation tailings, and the same will be shown by the four sacks of roasted Mount Cory ore shipped, from the second and third charges of these trials.

Should there be no difference in tailings from amalgamation and lixiviation, then the latter is preferable to the former, because a lixiviation plant is cheaper than an amalgamation plant, and the cost of operating them is in favor of lixiviation also.

ROASTING AND LIXIVIATION RESULTS IN FIGURES.

Charge I.—Ore from all the tunnels excepting "E."

Weight of charge	10,130	pounds	@ 38·64 ounces per ton	= 195·71	ounces.
Less flue-dust	340	"	@ 19·53 " "	= 3·32	"
Net charge	9,790	"	@ 39·30 " "	= 192·39	"
Ten per cent salt	1,077	"			
Net ore	8,713	"	@ 44·10 "	$57 per ton in silver.	
Weight of roasted charge	8,970	"	@ 39·50 "	per ton = 177·15 ounces.	
Weight of tub tailings (91 per cent and 9 per cent)	8,162	"	@ 3·63 " "	= 14·81	"
Therefore, leached out or obtained in sulphides, that is, bullion				162·34	"

We therefore have:

Bullion	162·34 ounces	= 84·3	per cent.
Loss in roasting	15·24 "	= 7·9	"
" tailings	14·81 "	= 7·8	"
	192·39 "	= 100·00	"

Not considering the loss in roasting, part of which no doubt, is flue-dust, remaining in the dust-chambers; and beginning with the roasted charge, as many mills do, we have:

8970 pounds charge @ 39·50 per ton	177·15 ounces.
Loss in tailings	14·81 "
Obtained in bullion (sulphides)	162·34 "

Which is equal to having obtained 91·6 per cent in bullion, and loss 8·4 per cent in tailings.

Charge II.—Ore from all tunnels except "E."

Weight of charge	9,890	pounds	@ 46·66*	= 230·73	ounces.
Less flue-dust	125	"	@ 34·11	= 2·11	"
Net charge	9,765	"		228·62	"
Less 10 per cent salt	868	"			
Net ore	8,897	"	@ 51·3 or $66.31 per ton.		
Weight of roasted charge	8,966	"	@ 41·65	= 186·71	ounces.
Sacked for amalgamation	240	"	@ 41·65	= 5·00	"
Net weight of charge worked	8,526	"		181·71	"
Tub tailings (91 per cent and 9 per cent)	7,758	"	@ 4·80	= 18·61	"
Obtained in sulphides (bullion)				163·10	"
Obtained in bullion				73·3	per cent.
Apparent loss in roasting				18·4	"
Loss in tailings				8·3	"
				100·00	per cent.

Or, if the roasted ore alone is taken to start with, we have 89·7 per cent bullion obtained, and 10·3 per cent lost in tailings.

Charge III.—Ore of tunnels C and D only. It was treated more carefully than the former two charges, and is therefore a fairer test to show what can be done by lixiviation, etc., with Mount Cory ore.

Weight of Charge III	8,282	pounds	@ 30·67 ounces	= 126·80	ounces.
Added flue-dust I	340	"	@ 19·53 "	= 3·32	"
" " II	125	"	@ 34·11 "	= 2·11	"
Total charge	8,747	"		132·23	"
Less 15 per cent salt	1,081	"			
Less flue-dust	32	"		0·42	"
Net ore	7,634	"	@ 34·7 ounces	= 132·81	"
Weight of roasted charge	8,411	"	@ 30·03 "	= 126·27	"
Sacked for amalgamation	242	"	@ 30·03 "	= 3·63	"
Net charge worked	8,169	"		= 122·64	"
Tub tailings (88 per cent and 12 per cent)	7,188	"	@ 2·62 ounces	= 9·41	"
Sulphides obtained (bullion)				113·23	"
Obtained in bullion				87·7	per cent.
Loss in roasting				5·0	"
" tailings				7·3	"
				100·00	per cent.

Or, if we start with the roasted ore, we have obtained 92 per cent in bullion, and lost 8 per cent in the tailings.

* This roll sample is unreliable, owing to a mistake having been made in sampling, which, when discovered, could not be rectified any more.

RECOMMENDATIONS FOR MOUNT CORY PLANT.

Taking these results, as a whole, I would recommend rolls, cylindrical furnaces, and leaching as against stamps, Stetefeldt furnaces, and amalgamation. A Stetefeldt furnace, as stated before, will work cheaper than a cylindrical furnace, and either cheaper than all the rest of known furnaces; but rolling ore and leaching it is cheaper than stamping and amalgamating it. The running cost in either case, I think, will be alike, but the cost of the plant with rolls, cylindrical furnaces, and leaching vats is cheaper than stamps, Stetefeldt furnace, and pans.

Respectfully yours, ALBERT ARENTS.

Mr. Stetefeldt says in his article, at about the 40th line from the beginning: "So far, the conclusions of Mr. Arents have my earnest support. When, however, he proceeds to wipe the Stetefeldt furnace out of existence with a stroke of his pen, it is," etc. What an unnecessary scare he allowed himself to get into! I do not wish to rob the Stetefeldt furnace of its merits, as any body may plainly see who reads my report with an unprejudiced eye, nor the Stetefeldt Company of its income by way of royalties. I have always considered the Stetefeldt furnace a valuable apparatus for purposes of chloridizing, from the record it has made; but I know of no case where said furnace has treated ores so coarse as not to pass a forty screen. Now, I desire to roast the Mount Cory ore in a much coarser state than that just mentioned, and do not feel inclined to build a Stetefeldt furnace for that purpose, because I am not sure but I might find, in starting up, that coarsely-crushed ore, ore that was crushed through a 16 or 20 screen, would fall so quickly through the shaft of the Stetefeldt furnace that it might reach the bottom before all its sulphur even is oxidized. I do not mean to say that the Stetefeldt furnace can not roast such material; but I do mean to say that I can not afford to experiment in this direction for the benefit of the Stetefeldt Company, when said company does not pay the expenses. Let Mr. Stetefeldt demonstrate by actual current work that this furnace does roast much coarser material than it heretofore has been roasting, and I shall be the first person to advocate its use for the purpose.

Mr. Stetefeldt's "analysis" of a small portion of my report, which he calls "the two rules of Mr. Arents," is any thing but just and sensible, because he interprets the portion first to suit his own purpose and then attempts to refute his own interpretation. This part of his article deserves no answer; yet, to gratify his desire for a reply, I will answer it. He makes four divisions:

1. He attempts to prove that Krom steel rolls will produce very finely-divided material up to dust. As far as the latter material is concerned, I bear testimony myself that Krom's rolls produce plenty of dust; for I never was in as dusty a place, the cooling-floor of the Stetefeldt furnace in the Northern Belle mill excepted, as the Bertrand mill roll-room is. That would be a sufficient proof, I suppose, for Mr. Stetefeldt to know that Krom's steel rolls produce pulp of any desired fineness for practical purposes, but it is not for me. On closer inspection and inquiries, I found that Krom's steel rolls, excellent as they are in every respect in comparison with all other rolls, which in course of time came under my observation, suffer from the same evil other rolls suffer from, namely, from uneven wear on the surface of the rolls. The consequence is, that the rolls, after a certain time, become grooved, like all other rolls. They may be turned off, as a matter of course; but during the time from one turning off to another, grooves of more or less extent will exist, which will prevent the rolls of proper capacity from practically and economically crushing ore to such fineness as is required for amalgamation or as dry crushing batteries usually produce. Of course, when I say this, I have two, or at most three, sets of rolls in view. I am, however, of opinion, that by increasing the number of sets of rolls, and forcing each set to crush all ore to a certain given and uniform size by providing each set with a screen of its own, the screens decreasing in size of mesh up to the finishing rolls, Krom's rolls will economically crush to any desired fineness; for at all events, the grooves in any set of rolls can never be as deep as the largest sized pieces of rock fed to it are in diameter. Each succeeding set of rolls will thus receive finer material for renewed crushing than its preceding set received, and each set receiving uniform material at all times, the grooves on each succeeding set will therefore be less deep. We have it thus in our power, in spite of the evil mentioned, to make Krom's rolls, or in fact any rolls arranged in the manner indicated, crush to any desired fineness without turning off. But a large number of sets of Krom's rolls, as required for such an arrangement, have a tremendous capacity, and are very expensive and therefore undesirable for the Mount Cory mill. I find by experiments that two or three sets of rolls crushing through a 20 or 30 Krom screen will do better than stamps; but beyond that fineness, stamps are preferable, according to Mr. Belding's results.

2. I wish to state that, when I speak of finely-divided pulp, I mean such pulp as is generally used in amalgamation and in Stetefeldt furnaces; that is, pulp crushed through a 30 or 40 screen. Just such finely-divided pulp as I state in my report is necessary for amalgamation, Mr. Stetefeldt himself bears testimony to. Such pulp is necessary on account of settler work, as he correctly states. Very well, what does Mr. Stetefeldt want? Is settler work not a part of the process of amalgamation, of which I speak in my report?

3. I wish to state that the chief silver-bearing mineral in the Mount Cory ore is its galena, a galena highly argentiferous. When that is roasted and chloridized, each particle of galena becomes practically a small mass of sulphate of lead, intimately mixed with chloride of silver. Both substances probably form a fused or semi-fused mass, hard to dissolve. At any rate, it is an established fact that the leaching of Mount Cory ore is a slow process in comparison with leaching in other localities. Leaching ore is dissolving solid material in an aqueous medium, and I take it to be an established principle, learned by experience in thousands of cases, that the dissolving of any thing does not practically take place unless motion between the dissolvent and the substance to be dissolved takes place; and furthermore, that the more vigorous the motion is, the more energetic is the dissolution. Now, if this is so, it follows that the liquor intended to dissolve the silver should pass very freely indeed through the mass of roasted ore. A speedy and copious percolation of the liquor, weak as it may be, should take place, in which conclusion I am supported by practical experience. I have furthermore experimented in my laboratory with Mount Cory ore in regard to leaching, and found that, the finer the ore was, the slower was the filtering and

Digitized by Google

the extraction thereby of both silver and lead. When I say, then, in my report, that, "after roasting such fine pulp, amalgamation must follow," it is plain that I mean that, although leaching finely-crushed pulp is possible, it is at the same time inexpedient, at least with Mount Cory ore, and that then amalgamation is preferable.

Had I written a scientific dissertation on the subject instead of a simple report, I should have made the above explanations and perhaps a good many more; but in a report to parties who are simply interested to know, as I understand them, how to turn their ore to the most profitable account, theoretical explanations are out of place. Such explanations, under such circumstances, may accord with Mr. Stetefeldt's methods, but not with mine.

4. Mr. Stetefeldt treats of his greatest grievance, to wit: I don't believe that a Stetefeldt furnace can roast ore coarsely crushed. I have already mentioned this point above; but I will say once more here, how glad I shall be to learn that the Stetefeldt furnace can accomplish this feat. But before I shall be sure of its ability to do it, I wish to have it demonstrated in an unmistakable manner. Mr. Russell's experiments in this direction are interesting; but I was till now not aware of them, and I wish to see them first verified by current work.

Now as to the economical question, the only one of practical interest. I will state that the cost of treating a ton of ore is at the Bertrand mill thirty per cent cheaper than at the Northern Belle mill, although the latter mill is crowded to its utmost capacity, and treats more ore, and effectively treats it, than any other mill of its size I know of. It is true, labor and wood are dearer at the Northern Belle mill than at the Bertrand mill; but both are of better quality too at the Northern Belle mill. Yet I have been very liberal to the side where the Stetefeldt furnace works; for I have called cost of treatment of Mount Cory ore even in each case; and when I recommend the treatment of Mount Cory ore by rolls, cylindrical furnaces, and leaching, I do it only on the score of cheaper plant. Respectfully yours, ALBERT ARENTS.

ALAMEDA, CAL., June 26.

THE WORKING OF STRONTIAN IN SICILY.

The recent introduction of strontian into the manufacture of tuyeres has given considerable importance to this mineral, which is comparatively scarce. Besides the deposits in Westphalia, those of Sicily are rather extensive, as to the working of which the *Chemiker-Zeitung* gives the following details: "The *celestine*, or sulphate of strontian, is found at Favara, near Girgenti, in the strata of the lower Miocene rocks, which in Sicily generally contain sulphur. These strata consist of limestone, calcareous marl, and gypsum, in the midst of which the sulphur is disseminated, generally in the form of fine powder, and more rarely in nodules the size of a pea or nut. At Favara, sulphur is not present to any great extent, but is partly replaced by sulphate of strontian. The upper strata of the rocks, which are mainly horizontal, are decomposed by the action of the air; the light mineral particles are carried along by water, while the *celestine*, which is heavier, and therefore less liable to be carried away, remains in blocks on the surface. In appearance, it differs but little from the limestone with which it is associated; but it is easily distinguished by its greater specific gravity (3·9), on account of which it has received the local name of *cuchiommo*, from *come piombo* (like lead). The ore is at present only worked open-cast at Favara, no regular mine workings having yet been attempted. The inhabitants of the region lead it down to the railroad stations at Girgenti or Palermo, where it is bought by merchants at 35 lire (28s.) a ton. At Porto Empedode, it is screened, to free it from the gangue, and then shipped for Hamburg and other ports. In 1880, only 1000 tons were exported; but in 1881, the production increased to 4000 tons. Works are now going up at Rosslau, in Alsatia, for the conversion of the Sicilian ore into caustic strontian and carbonate of strontian, this latter (strontianite) not being found in Sicily."

LOADS AND STRAINS ON HOISTING ROPES.

Mr. W. Silver Hall, of Derby, England, writing to the *Engineer*, gives the following interesting facts, and makes suggestions which in many instances American engineers would do well to follow:

Some years since, I had a winding rope broken about three feet above the cap, in the act of raising the loaded cage from the props; in fact, the cage was raised, and fell about two and a half feet, as nearly as could be estimated. The weight of cage, tub, coal, and chains, with the cap and piece of broken rope, would be 75 or 76 cwt.; the weight of rope suspended in the shaft, 32 cwt.; total, 108 cwt. The rope was a flat one, of iron wire, tapering from 4¼ inches to 4¼ inches wide, giving a breaking strain of 60 tons and 50 tons, and a safe working load of 186 cwt. and 112 cwt. at the upper and lower ends respectively. It had only been in use a few weeks, and there was no sign of any flaw at the point of rupture. After the torn end was cut off, and the rope re-capped, it continued to do its work satisfactorily for the full average life of the ropes at that pit. The engine, although a single-cylinder one, was remarkably easy to handle, and the engine-man one of the steadiest and most skillful that I have known. The rate of winding, though smart, was not excessive, the run of 202 yards being made in 30 seconds, and the three-decked cage changed in 30 seconds; or, allowing for occasional delays, say 55 runs per hour.

At first sight, the rope might have been expected to break at the top end, where the actual weight to be lifted was nearly 80 per cent of the theoretical safe working load, rather than at the bottom end, where the weight was only 68 per cent of the theoretical safe load; but when it is remembered that the 32 cwt. of rope is already in rapid ascending motion before the "snatch" comes to start the 76 cwt. of cage, etc., into motion, it is apparent not only that the rope actually did break where the severest strain came upon it, but also that that strain is very much nearer to the actual breaking strain than is commonly supposed.

A mere record of facts, such as the above, is not of much value unless it leads to the suggestion of some improvement in the appliances, or in the method of using them, calculated to obviate similar accidents in the future. One such suggestion, and the most obvious, is the substitution steel for iron ropes, giving, with a rope of the same weight, an increased strength of some 50 per cent; but of course at a considerably increased cost. To employ a stronger and, consequently, heavier iron rope, would have the effect of striking an up-hand blow with a heavier hammer than before. Again, it is doubtful whether, for pits of moderate depth, the advantages obtained by a tapered rope are not purchased too dearly by the weakness at the bottom end, where, as we have already seen, the greatest strain comes at the moment of starting. Now, where the suspended weight of rope is counterbalanced by a tail rope—which, as I pointed out at the Leeds meeting of the Institution of Mechanical Engineers, in August last, can probably be economically applied in cases where the depth does not exceed 500 yards or thereabouts—the weight on the rope is constant at any stage of the winding and, consequently, a parallel rope is the right thing.

But perhaps the most important point of all is to diminish, as far as possible, the dead-weight snatched at by the rapid starting of the engine, and this can only be done by using the lightest possible trams and cages. In the instance above given, if the cage had been of steel, instead of iron, its weight might probably have been reduced 30 per cent or more—and I could point out instances where a much greater reduction has actually been effected—thereby reducing the total weight to be snatched at, that is, coal, tubs, cage, and chains, by about 12 per cent. But while cages are only too often considered as a convenient stock job, on which the colliery smith may advantageously employ the olds and ends of his time, and expend such bars of iron as he happens to have no other use for; while they are too often commenced, continued, and finished without any harmonious design or plan, but by the addition of one part after another, each fulfilling its own object, and adding to the total weight, but not contributing to the aggregate strength of the structure; while some of the parts most severely strained are too often weakened by injudiciously placed bolt or rivet-holes, and when they fail are replaced by stouter bars and bigger rivets, the result can scarcely be satisfactory in any respect, and least of all where lightness is desired. Perhaps the next attempt is made in steel, with a result more disappointing than ever, and that ill-used material, as I have too often found when advocating its use, is for ever discredited in the eye of the disgusted proprietor.

As there is no difficulty in making a properly designed steel cage which for any given weight of coal to be lifted shall be from 25 to 50 per cent lighter, and shall cost no more than an iron one, it is surely time that the state of things which I have endeavored to describe, and which, as every mining inspector knows, is only too common, should cease to exist.

GLASS-BLOWING BY COMPRESSED AIR.

Engineering describes a process for dispensing with mouth-blowing in glass manufacture, which has been in use at the Clichy Glass-Works of MM. Appert, in Paris, since 1879. The first in France to employ compressed air for glass-blowing was probably an *ouvrier* named Baccarat, who, in 1824, invented a small mechanical blower. Appert's apparatus is capable of blowing the largest pieces of glass; and it is extremely valuable from a humane point of view, as it prevents those maladies of the glass-blower which arise from forced expiration, and breathing hot dry air. The apparatus, as described to the French Academy of Sciences, consists of two conjugate compressors put in action by the shafting of the works, and storing compressed air in reservoirs sufficient to serve twelve hours. It is distributed to the blowing apparatus by pipes with cocks, and controlled by a pressure regulator. In the Clichy works, the air is employed under three pressures—one of 42 pounds per square inch, one of 14 pounds per square inch, and one of 2·85 pounds per square inch. The last pressure serves for the construction of goblets, jugs, etc., lighting-lamps, bottles, and so on. The air is supplied to the glass by giving it an axial rotation similar to that of the blow-pipe. The latter is fitted with a stop-cock by which the workman can regulate the air supply. The glass is rotated either on horizontal or vertical axes, to suit the class of work. As the preacquired habits of the workmen have been consulted in this new apparatus, they readily become used to it. The new machines enable the manufacturers to dispense with a number of the children formerly employed in this injurious work.

PHOSPHORUS IN NICKEL.—Pure nickel, after melting and casting, generally holds a greater or less quantity of oxygen in combination, and the metal is brittle. To hinder the injurious effects of the oxygen, it is necessary to incorporate in the melted nickel some substance which has a strong affinity for oxygen, and also for the nickel itself. According to the *Comptes Rendus*, M. J. Garnier finds that phosphorus serves both of these purposes very satisfactorily, producing effects analogous to those of carbon in iron. If the phosphorus does not exceed three tenths of one per cent, the nickel is soft and very malleable; above this quantity, the hardness increases at the expense of the malleability. Phosphorized nickel, when alloyed with copper, zinc, or iron, gives results which are far superior to those that are obtained from the same nickel when not phosphorized. By means of the phosphorus, Garnier has been able to alloy nickel and iron in all proportions, and always to obtain soft and malleable products. The contradictions of illustrious chemists are thus explained, some saying that such alloys were brittle, others that they were malleable. The latter had alloyed the nickel to phosphorized iron.

THE TRANSPORTATION OF EXPLOSIVES.—In commenting editorially on the report of the British Inspectors of Explosives, the *Ironmonger* says: In respect to the packing and conveyance of explosives, a curious case is cited in support of the contention that packages containing dynamite must be thoroughly water-proof. This was a case in which a cart containing dynamite of foreign make, while conveyed across the Duddom Sands from Millom to Dalton, stuck fast in a quicksand, and the water caused the nitro-glycerine to exude to such an extent that the dynamite had to be blown up on the sands. The inspectors, again, condemn the "false policy" of the railroad companies in refusing to carry various explosives under any conditions, as leading to surreptitious conveyance of the prohibited articles, and they cite an example in which 300 pounds of blasting gelatine were conveyed by a passenger from Newcastle to London by passenger train, then across London by cab, and again by rail to Whitstable. This "handy little earthquake," it may be remarked, was conveyed, for the most part, in a second-class smoking-carriage!

FURNACE, MILL, AND FACTORY.

The following is a partial list of the awards for the best displays at the Chicago Exhibition: Logging and mining locomotive, gold medal, H. K. Porter. Locomotive involving important new principles, gold medal, Philadelphia & Reading Railroad Company. Steam gauge, silver medal, Ashcroft Manufacturing Company. Wire cloth, bronze medal, Clinton Wire Cloth Company. Boiler rivets, bronze medal, Hoopes & Townsend. Locomotive steel forgings, gold medal, Midvale Steel Company. Locomotive and car iron forgings, silver medal, Wilson, Walker & Co. Pressure gauge, silver medal, Yale & Towne Manufacturing Company. Coal, ore, or gravel dump-car, silver medal, U. S. Car Company. Steel axle (master car-builders' standard) silver medal, Midvale Steel Company. Iron axle (master car-builders' standard), silver medal, Pittsburg Forge and Iron Company. Spring (elliptic), gold medal, A. French & Co. Springs (bearing), silver medal, A. French & Co. Springs (buffer or draw), bronze medal, French Spiral Spring Company. Steel tire for car wheels, gold medal, Midvale Steel Company. Steel tire combination wheel, gold medal, Allen Paper Car Wheel Company. Iron working tools (power), not less than six in number, grand gold medal, Pratt & Whitney Manufacturing Company. Axle-turning machinery, silver medal, Machine Tool-Works. Car-wheel boring and turning-machine, gold medal, Machine Tool-Works. Six-spindle drilling-machine, silver medal, Niles Tool-Works. Hydraulic wheel press, silver medal, Machine Tool-Works. Wheel-grinding or trueing machine, silver medal, Chilled Car-Wheel Grinding Company. Iron planing-machine, silver medal, Machine Tool-Works. Iron crank-shaping machine, silver medal, Pratt & Whitney Manufacturing Company. Screw-cutting engine lathe, silver medal, William Sellers & Co. Upright drilling-machine, silver medal, William Sellers & Co. Radial drilling-machine, silver medal, Machine Tool-Works. Bolt-heading machine, silver medal, National Machinery Company. Bolt forging machine, silver medal, National Machinery Company. Bolt and screw cutting machine, silver medal, National Machinery Company. Set-screw machine, silver medal, Pratt & Whitney Manufacturing Company. Power hammer, silver medal, Machine Tool-Works. Power punch and shears, silver medal, Hercules Iron-Works. Planer chuck, silver medal, Pratt & Whitney Manufacturing Company. Universal and independent chuck, over twelve inches in diameter, silver medal, E. Horton & Son. Universal lathe chuck, twelve inches and under, silver medal, E. Horton & Son. Assortment of lathe chucks, silver medal, E. Horton & Son. Assortment of planer chucks, silver medal, E. Horton & Son. Display of emery grinding machinery, silver medal, Northampton Emery Wheel Company. Display of machinist's vises, silver medal, Fisher & Norris. Display of taps and dies, silver medal, Pratt & Whitney Manufacturing Company. Nut-tapping machine, silver medal, Shumway, Burgess & Co. Drill-grinding machine, silver medal, William Sellers & Co. Slotting machine, silver medal, Machine Tool-Works. Driving-wheel lathe, gold medal, William Sellers & Co. Shafting, gold medal, Jones & Laughlins. Hanger, bronze medal, Jones & Laughlins. Pulley, bronze medal, Jones & Laughlins. Flue welding device, bronze medal, Hartz & Fix. Portable power drill, bronze medal, Thomas H. Dallet & Co. Spring tester, silver medal, Tinius Olson & Co. Display of tools for repairing locomotives, silver medal, Flanders Machine-Works. Hot-air pumping-engine, silver medal, C. H. Delamater & Co. Machine for testing strength of metals, gold medal, Fairbanks, Morse & Co. Vertical boring-mill, silver medal, William Sellers & Co. Horizontal boring-machine, silver medal, William Sellers & Co. Steel and iron rails and track goods, grand gold medal, Cambria Iron Company. Track bolt and nut, bronze medal, Hoopes & Townsend. Track bolt-washer, bronze medal, Pratt Manufacturing Company. Car-wheel iron, gold medal, Barnum, Richardson & Co. Flanging iron, silver medal, Eureka Iron Company. Boiler plate (iron), silver medal, Eureka Iron Company. Display iron ores, gold medal, Barnum, Richardson & Co. Steam-pump for water station, gold medal, Fairbanks, Morse & Co. Hand pump for water station, bronze medal, Fairbanks, Morse & Co. Hydraulic ram, bronze medal, J. B. Clow & Son. Track scale, gold medal, Fairbanks, Morse & Co. Platform scale, silver medal, Fairbanks, Morse & Co. Rubber belting, silver medal, Hamilton Rubber Company. Surveyor's transit, silver medal, W. Jordan & Son. Surveyor's field glass, bronze medal, L. Manasse. Display of surveyor's instruments, gold medal, Keuffel & Esser. Variety of engineer's drawing tools, bronze medal, L. Manasse. Engineer's level, bronze medal, W. Jordan & Son. Engineer's barometer, bronze medal, L. Manasse. Set of engineer's railroad curves, bronze medal, Keuffel & Esser. Leveling rod, bronze medal, Keuffel & Esser. Prismatic compass, bronze medal, L. Manasse. Tube welding machine, bronze medal, Manning, Maxwell & Moore. Cupola, silver medal, Colliau Furnace Company. Malleable iron castings, bronze medal, Cleveland Malleable Iron Company. Fire-clay brick, bronze medal, Denver Fire-Brick Company. Power blower, silver medal, Boston Blower Company. Power pressure blower, silver medal, Wilbraham Brothers. Portable forge, bronze medal, Buffalo Forge Company. Hand blower, bronze medal, Buffalo Forge Company. Cold-pressed nut, silver medal, Hoopes & Townsend. Display of nuts, bolts, rivets, etc., gold medal, Hoopes & Townsend. Copper boiler and flues, silver medal, American Tube-Works. Seamless copper pipe, silver medal, American Tube-Works. Seamless brass pipe, silver medal, American Tube-Works. Elevator buckets, bronze medal, B. F. Gump. Rawhide belting, silver medal, Chicago Rawhide Manufacturing Company. Cotton belting, silver medal, Gandy Belting Company. Boiler and pipe covering, silver medal, Shields & Brown. Hot pressed nut, silver medal, J. H. Sternburgh.

The Wetherill Steel Casting Company has been organized at Chester, Pa., with $500,000 capital stock, and will build steel-works in that town.

An iron draw is about to be shipped from Paterson, N. J., to the Northern Pacific Railroad for a bridge over the Snake River, Oregon, which is said to be the longest and heaviest double-track draw ever built, being 345 feet long and weighing 450 tons. Another, to span the Willamette River, Oregon, is to be 390 feet long and made mostly of steel. The cost of this will be in the neighborhood of $90,000.

The business of the Jarvis Furnace Company and the New England agencies of the Korting injector, Armington & Sims Company engines, Sheffield grate-bars and Schuttee & Goehring's jet instruments, will in the future be conducted by a stock company organized under the State laws of Massachusetts, with a capital of $100,000. This company will do business under the name and style of the Jarvis Engineering Company. It will not only take charge of the old agencies, but it will do a general engineering and contracting business in putting in steam plants for all kinds of manufacturing purposes. Mr. K. M. Jarvis, of Boston, will be president; A. F. Upton, of Boston, treasurer and general manager. The directors will be K. M. Jarvis, A. F. Upton, L. B. Wright, Boston, Mass.; H. A. Glasier, Springfield, Mass.; F. H. Pond, St. Louis, Mo.; and J. A. Grant, secretary and clerk.

Broad & Ewer, Progressive Iron-Works, are getting well established in their new shops, Nos. 251 to 255 Greenpoint avenue, Brooklyn, N. Y. They are at present building six of the Parson & Northey grinders and amalgamators for precious ores, each of which is to be complete, with steam-engine for driving. This company also manufactures the Van Dyke water-tube boiler.

At Worcester, Messrs. C. Stewart & Son are making and have orders for steel boilers from more than a dozen different places in and out of New England. They use the "Nashua" brand of steel, made at Nashua, N. H., which is stamped 60,000 pounds tensile strain, and equal to the best.

The Russell Hardware Company, with Charles T. Russell as president and $150,000 capital, is going into business at Higganum, Conn. It will employ from 50 to 75 men, and controls a number of valuable patents.

The cylinder-head of one of the large engines at Graff, Bennett & Co.'s Millvale mill blew out last week.

The large sewing-machine factory at Downingtown, Chester County, Pa., has been bought by Philadelphia parties, and is to be converted into extensive stove-works.

The Helmbacher Forge and Rolling-Mills Company, of St. Louis, has added another hammer to its works, which makes its plant now six hammers. It has also put in a new 75-ton testing-machine.

Messrs. Osgood & Co. are building some new spelter furnaces at their Bergen Port works.

GENERAL MINING NEWS.

ARIZONA.

GRAHAM COUNTY.

A discovery of galena ore was recently made in a claim half a mile south of the Detroit copper mines. The croppings are well defined and can be traced for a long distance. The formation is lime. A shaft was sunk on the vein six feet in depth, an assay of the ore going 40 ounces silver. The vein, which is narrow on top, promises to widen as depth is attained.

At a point about thirty miles from Clifton, between Eagle Creek and Blue River, a party has located a number of claims, the ore from which is sulphurets, and carries gold that can be seen with the naked eye. After making these locations, the party journeyed eastward, and prospected the range bordering the Blue to the westward. Here they made four locations, the samples of the ore brought in being sulphurets and yellow chlorides. The formation is quartzite an porphyry.

CALIFORNIA.

MONO COUNTY—BODIE DISTRICT.

The reports from the leading mines of this district show no important change. The usual amount of development-work has been done, and the production remains as usual.

PLUMAS COUNTY—GREENVILLE DISTRICT.

GOLD STRIPE.—During the past week or more, ore-hauling to the mill has been steadily going on. The dump is now pretty well filled up, and the mill will probably be started up in a few days.

SIERRA COUNTY.

MARGUERITE.—The mine is steadily improving.

RAINBOW.—It is stated that this property has been sold. The company intends to begin the work of running a new tunnel this season. This tunnel will be run from Kanaka Creek, and will tap the ledge in 2500 feet. Burleigh drills will be used, and the work will be pushed ahead as rapidly as possible.

SIERRA BUTTES.—A force of men is engaged in excavating for the foundation of the new mill to be erected on the river by this company.

CANADA.

PROVINCE OF NOVA SCOTIA.

A dispatch from Halifax says that a cablegram from London announcing the formal decision of the Judicial Committee of the Privy Council sustaining the appeal of C. F. Mott and others in relation to the Salmon River gold mines was received July 2d by the appellants.

CENTRAL AMERICA.

NEW YORK & HONDURAS-ROSARIO.—The official reports from the mines of this company continue very favorable. All the headings in the Rosario mine are said to be in good ore. East of the main shaft, between the fourth and fifth levels, the superintendent reports ready for extraction a solid body of ore 75 feet long and 100 feet deep (the vein averaging 3 feet thick), estimated to contain about 2000 tons of rich ore. The New York still shows the bonanza ore previously reported. The explored body is now 300 feet long, and the ore is of uniform grade. The headings of the two cross-cuts are in good ore, though not so rich as that of the main body. The tunnel intended to connect the New York and American mines will be completed in a short time and will facilitate considerably the extraction of ore from these two mines. The Matraca and Encinos are in the same body of rich ore, but none of the ore has been extracted for want of room on the dumping-grounds. After serious and unexpected delays, the new mill is running. The pans save eighty per cent of the bullion. Bullion valued at $1800, the result of a few broken days' run, has been received in this city, and more bullion is expected by the company per next steamer.

COLORADO.

CLEAR CREEK COUNTY.

GOLD LEAF.—This property was first discovered over a year ago, and was purchased by the present owners, who traced the lode by open cuts from three to six feet in depth and from twenty to thirty feet in length on the surface. The ore prospected so well in panning that several tons were sent to various points to be treated by both smelting and free milling. The proceeds of the ore paid nearly the entire expense. There are now a number of drifts, and an incline shaft on the vein to a depth of 90 feet, and it is still driven ahead. This incline is started near the apex of the hill. About 150 feet below, another drift is running, which will strike the incline at a depth of 150 feet. A stamp-mill, with grinding-pans and settlers to work the ore, is now in course of erection at the mine. The machinery is upon the ground, the frame of the mill is up, and the workmen are inclosing it as fast as possible. Fine ore was gathered from three different places on the vein, which panned out surprisingly rich. The mill is expected to be in readiness by the middle of July. But one battery will be put in at present, and extensions made as the property may demand. This property consists of three claims, being 4500 feet in length by 150 feet in width. The ore is a decomposed quartz, with a heavy seam of iron stain and rust, in places fully five feet in thickness. Only development-work has been done, yet there are hundreds of tons on the surface awaiting the completion of the mill.

MOLINE.—The tramway is completed. It is 2500 feet long, and has twenty-two stations. At each end is a horizontal wheel, around which the endless cable passes. Fifty buckets are attached at intervals of 100 feet. Each carries from 100 to 150 pounds. An entire revolution is made in less than forty minutes, so that two and a half tons are moved at each revolution. Forty tons can be easily trammed in ten hours, and this can be increased by adding buckets up to the sixteen-ton capacity of the cable. The whole affair has been invented and built in the past three months.

MONTREAL.—In order to work the property more successfully in the future, it was considered advisable to work it through a tunnel or adit on the vein, which has been run 300 feet and gained a depth of 150 feet. The mineral showing is well, and a shaft is sinking.

PERKINS TUNNEL.—The recent rich gold strike has been sold for $10,000. Development-work will be started immediately.

GUNNISON COUNTY.

BULLION KING.—A company has been organized, with a capital of $150,000, 15,000 shares, at $10 per share. Machinery has been ordered, and as soon as it is ready, work will be begun to sink the incline shaft one hundred feet deeper.

FOREST QUEEN.—A contract has been entered into with the Rose & Reed Milling Company, by which the latter takes all the ore produced.

LAKE COUNTY.

Late Leadville exchanges contain the following:

ADLAIDE.—The lessees have opened up a large body of ore. The parties are working the mine through No. 2 shaft. The mine at present shows a ten foot

Digitized by Google

face of ore, and, with increased hoisting capacity at the No. 2 shaft, the lessees should be able to make an output of twenty or thirty tons of ore a day. The mineral is stated to be of very fair grade, and will net the company a good profit.

ALLEGHANY CONSOLIDATED.—The southern portion of this property has been leased to Messrs. Sanderson & Abbott, of Denver, for one year. The lease embraces the Right Angle and Rarus shafts. Machinery has already been ordered, and work will begin at once.

BROOKLAND.—Shipments have been resumed.

COLONEL SELLERS.—Shipments are very light at present, and will continue so probably until the litigation is ended. The new body of carbonates recently found is showing up well.

IRON HAT.—The lessees are meeting with good success. During the past month, they shipped about 250 tons of ore, while their property now shows fair resources. The lessees sunk a new shaft on this mine, which adjoins the Iron mine, when the lease was awarded them, and at twenty-eight feet encountered the contact. Pursuing exploration-work, mineral of paying quality was soon after encountered, and regular shipments followed. A second shaft has since been sunk to a depth of fifty feet, and drifting begun.

LA PLATA.—For the past year, this mine, the property of the La Plata Mining and Smelting Company, has averaged a daily production of thirty tons, including Sundays, and at present the property is turning out about fifty tons a day. The product of the mine is of fair quality, and particularly desirable as a smelting ore on account of the large percentage of lead and iron that it carries. The most extensive resources of the mine are large bodies of ore situated in the limestone. Very fine ore-faces are also presented in the extreme southern portion of the property, where developments are on a lime roll, and there are prospects of opening a large chute of ore within a short distance.

LITTLE ELLEN HILL.—A large amount of work is doing on the mines of Little Ellen Hill, and scarcely a shaft can be found in this section that is not working. Considerable ore is also taken out, and at all times of the day ore teams can be seen on the road between the mines of the hill and the smelters in Big Evans and California gulches. The mineral resources of Little Ellen Hill are fully as extensive as those of any other section of the Leadville District, and it is only due to the low grade of the ores, which prevented their profitable shipment until within the past year, that the mines are not as extensively worked as those of Carbonate or Iron Hill. Now, however, all of the properties are working large forces, and extensive ore-shipments are made which return very fair net profits. Among the most prominent are the Little Ellen, owned by the American Mining and Smelting Company, the Opulent, and the Virginius mine.

RUBY.—Three fourths of this mine were recently sold for $60,000. The purchasers have organized a company, to be known as the Savannah Mining Company. Operations on the property are to be commenced at once.

PARK COUNTY.

The Fairplay Sampling Works, owned by the Van Dusen Brothers, having recently put in new and improved machinery, are running to their full capacity and giving universal satisfaction.

LONDON.—The new twenty-stamp mill has been running very successfully. The ore being mostly free-milling gold quartz, the pulp is run off over plates, which process is supposed to work well so far as the saving of gold is concerned, although no reliable tests have yet been made. The battery samples of the quartz run under the stamps returned $48 in gold and $12 in silver to the ton. At present, the tailings are run into tanks, but experiments are now going on, and as soon as a conclusion can be arrived at as to the proper concentrating machinery to be used, concentrators will be put up, and the silver and also the gold escaping over the plates will be saved in this process. The mill is a few miles below the mine, and is connected by a railroad. At the end of the track, an automatic tramway forms the connection between the railroad cars and the mine, thus avoiding any second handling of the ore from the time it leaves the stopes until it reaches the self-feeders in the mill. The mine contains about 4500 linear feet of drifts, winzes, and rises. About forty men are employed.

PITKIN COUNTY.

THORNBURG.—This company, recently organized, has purchased the Mineral Farm mine and several other properties in its vicinity. Work has already begun and about fifty men are employed.

SUMMIT COUNTY.

BELDEN.—The prospects of the mine are favorable; the production is increasing; and as soon as the tramway, which is going up from the mine to the railroad, is finished, shipments will regularly be made.

KEYSTONE BULLION.—The smelter has been doing well during the experimental work of the past four weeks. All the concentrating machinery is operating satisfactorily. The large amounts of concentrating ore in this district will find a market at Breckenridge until works are erected at the different mines.

RED PEAK MINING DISTRICT.

This district, opened about two years ago, is showing considerable activity, and the season begins with the promise of resulting in numerous valuable developments. The district embraces an area about thirty miles in circuit, including the North, Middle, and South Willow creeks, also Rock and Gore creeks. A large number of veins have been discovered, and on an average have been found to contain very high-grade ores. Developments up to the present time are limited. The pay-streaks in the veins are also small, but much is expected of future development-work. The principal mines are right on the naked peak. Among them are the following: Boss Tweed, Silver Vault, Defiance (continuation of the Silver Vault), Lost Boy, Anglo-Saxon, Highland Chief, Black Prince, Comet, Lady Godiva, Silver Mint, D. S. lode, Scarff lode, Ackermann, and Ruby Elva.

The Cañon lode, on the south slope of Red Peak, is a vein measuring from six inches to four feet of quartz, with chunks of native silver weighing from a quarter of an ounce to six ounces. One small seam carries oxide of iron with native silver in small grains and wire.

DAKOTA.

CALEDONIA.—The superintendent reports, June 17th: Ore produced, 985 tons. Gold bar shipped, $14,500. The winze has advanced 8 feet, making a total of 140 feet (100 feet vertical). We have begun enlarging the bottom of the winze to put the pumps in place and are getting ready to start cross-cutting. The mine in general is looking well and the machinery at the mill is running excellently.

FATHER DE SMET.—The superintendent's report for the week ended June 22d shows: Ore extracted from first, second, and third levels, 1950 tons; ore milled, 1950 tons. Golden Gate north header in 146 feet.

RICHMOND.—The company is running three shifts on two drifts from the bottom of its shaft. One, the east drift, is in solid ore of a very fine grade. Twenty men are at work.

GEORGIA.

BARLOW.—During the past week, the Howland mill has been set up, and will soon be started for a trial run.

CHESTATEE.—Forty stamps are run by day and twenty on the night shift.

FISH TRAP.—Two veins have been opened during the past week, the specimens showing free gold. The mill is again running on full-time.

GARNET.—The twenty-stamp mill now erecting on this company's property is almost completed. The building is of sufficient size to admit of the addition of another twenty stamps, which are to be added if developments warrant.

KEYSTONE.—According to the Dahlonega *Signal*, proceedings for foreclosure have been instituted; and in consequence, this property, which gives so much promise, must remain idle for an indefinite length of time.

LOUD.—A small force only is employed at this mine, and but little more than prospect-work is done.

IDAHO.

COLUMBIA & BEAVER.—The company's mill has started up on custom ore, of which there are several hundred tons at the Pilgrim, Columbia & Beaver, Silver King, and Bidwell mine-dumps. The mill men intend to charge $35 a ton for reduction, and will guarantee a yield of 90 per cent.

PHILADELPHIA MINING AND SMELTING COMPANY.—The additional buildings which have been in course of construction during the past six weeks at this company's works at Ketchum are nearly completed. They consist of two main buildings, the one 200 feet long by 50 wide, the other 60 by 60. Two new furnaces have been shipped. They will be blown in as soon as they are put in place. These, in addition to the two stacks already in operation, will give a smelting capacity of 180 tons per day.

MEXICO.

One of the greatest needs of Mexico at the present day, says the *Financier*, is the establishment of works in various parts of the country, upon an extensive scale and with the most approved modern appliances, for the reduction of the precious minerals. There is no better opening afforded to American capitalists for good investment, with large and absolutely certain returns, than by meeting this demand. It is said that during the past two or three years, over $10,000,000 of American money have been invested in mines in this country. Many large mines, of course, have their own reduction-works; but these are of little benefit to mining at large, since they are generally kept busy in reducing their own ores, and have not the capacity to accommodate custom-work.

The finest quality of white, mottled, and vari-colored marble is found in the great marble quarries near the city of Chihuahua.

BATOPILAS.—The company is putting up a new twenty-five-stamp mill and another roasting-furnace.

MAPIMI.—The experience of this company, in Northeastern Durango, with its new machinery, shows that modern facilities greatly increase the yield of the ore. With the old Mexican methods, the yield averaged $32 to the ton, but now the average is much greater. The new route of the Mexican Central Railroad will pass almost close to the mines.

NORTH MEXICAN MINING AND MILLING COMPANY.—This company has been organized to work the Hilo, Guadalupe, Ladero mines in Sonora. The ore carries chiefly silver. The mines are more or less developed. A stamp-mill and machinery are on the ground.

SANTA EULALIA.—Major Charles Hitchens has obtained the right to work over the slag. The company is pushing its development of the old mines vigorously. The new reduction-works near the railroad will be among the most complete in Mexico.

MICHIGAN.

The Marquette *Journal* gives the following table, which exhibits, in gross tons, the total lake shipments of iron ore from upper peninsular ports the present season up to and including June 27th, together with the amount shipped from the same ports during the corresponding period of last year:

Name of port.	1882.	1883.
Escanaba	525,748	362,723
Marquette	292,027	116,927
L'Anse	13,308	12,521
St. Ignace	7,499	.....
Total	838,582	492,171

Showing a decrease of 346,411 gross tons.

The hydraulic company which is now engaged to use the water-power at Little Quinnesec Falls, on the Menominee River, for driving the mining machinery of the Chapin and Ludington mines, about two miles distant, is hailed by local papers as a great enterprise.

ISHPEMING IRON COMPANY.—The company intends commencing work on its possessions in Marquette County in the near future. It possesses some valuable mineral-bearing tracts that will doubtless prove worth developing. A diamond drill will be employed in the search.

PENINSULA.—Machinery for exploratory work on the Pewabic lode is getting into place by this company, and sinking will soon be commenced. It is the intention to sink about 200 feet and thoroughly explore the main lode by drifting, as well as to determine the location, by cross-cutting, of branches or lateral deposits such as are found at the Quincy.

MINNESOTA.

MINNESOTA IRON COMPANY.—At the Breitung mine, one of this company's properties, about 3000 tons of ore have been mined and put in a stock-pile. This was taken out in the course of explorations made to determine the extent of the deposit. Considerable ore has been mined in the course of explorations made on other properties owned by this company, although no regular mining work has yet been attempted.

MISSOURI.

SUNNYSIDE.—This mine has been leased at a royalty of ten per cent. The lessee has sunk a shaft 35 feet deep, and the last 17 feet cut is a solid body of ore. A drift has been started from the bottom of a shaft, and the men are now cutting it. The water is light and easily managed. A lively excitement has sprung up already, and seven or eight shafts have been started down during the past week.

MONTANA.

GALLATIN COUNTY.

An important discovery of mineral has lately been made in the Emerson Mining District, just across the Jefferson River and about twenty-five miles west of Bozeman. The discovery can not properly be called a recent one, as a claim was staked off there thirteen years ago. But this spring, several miners went to prospecting the district, and the result is, some thirty locations have been made. The ore carries gold, silver, and copper, the latter predominating. Assays of the latter metal have given from 18 to 70 per cent, and as high as 240 ounces of silver have been received. The veins are about eight feet wide and have one well-defined wall, the other being somewhat broken and irregular. As there is not a twenty-foot shaft in the district, but little can be said.

HENRY VILLARD.—This company's property is opening up well. The gravel is 100 feet deep in some places.

SILVER BOW COUNTY.

PARROTT MINING AND SMELTING COMPANY.—At the annual meeting of the stockholders, held at Butte recently, the following directors were re-elected for the ensuing year: T. Hauser, A. M. Holter, and A. F. Migeon. Thomas Wallace was elected president; Franklin Farrell, managing director; and E. J. Gaylord, superintendent, secretary, and treasurer. A. F. Migeon, under whose superintendency the Parrott works were built and have since been operated, was, at his earnest solicitation, permitted to retire from the arduous duties of superintendent, a position which he is understood to have retained during the past year only under protest. The company starts on its new year in better shape than ever before, and will show good results before another election is held.

NEVADA.

The Peavine District, near Rome, at one time promised to be an important mining camp; but after a good deal of money had been expended, the place was abandoned. The *Gazette* says the ore is rich but rebellious.

DAY.—The lower levels of this mine have greatly improved during the

Digitized by Google

week. The large cave of ore recently struck has been sunk on to the depth of twenty feet.

ELKO CONSOLIDATED.—A twenty-foot ledge has been recently struck in the tunnel running in the ground lately purchased from the New York Company, but which has let it lie idle for years. The point at which the strike was made is 400 feet below the surface, and a considerable distance beyond the lead originally worked, which was left behind in the tunnel. The vein is 20 feet wide, of solid galena, and yielding from 45 to 49 per cent lead. It is estimated that at least 500 tons of such ore are now on the dump, and large quantities are in sight in the mine. In the mean time, a new and substantial furnace will be erected on the ground now occupied by the old one built by the Eastern Company years ago. It will be put in place immediately after the arrival of the necessary machinery, which is now on the way from the East.

LIMESTONE.—Work has just begun on this property at Bullion. There are 10 inches of high-grade galena and carbonate ore going straight down into the lime. The progress is eagerly watched. The Battle Mountain folks are talking of building a wagon-road to the Limestone Company's mines, in order to get shipments of ore for their new furnaces to run on.

MEADOW VALLEY.—A strike has been made in the old Fitzhugh tunnel. The ledge has been sunk on about six feet from the bottom of the tunnel, and is nearly four feet in width from wall to wall at the place where work was then going on. Some five tons of this ore were sent to the Dry Valley mill, and the pulp-assay went $44 in silver and $6 in gold, the total pulp-assay being $50. This discovery is nothing new. The workings of the mine show this. The ore above this point was all extracted years ago. The ore had all been extracted down to the tunnel level in early days, then becoming low grade, it was abandoned.

RUBY HILL TUNNEL.—The tunnel is in 304 feet, and a contract is about to be let to run 100 feet more. After passing through the iron seam 270 feet in, nothing else of a noteworthy character in the formation has been encountered. The ventilation continues to keep the air fresh and sweet.

SILVERADO.—The dump of ore belonging to this company, which came out of the property formerly known as the Rescue mine, has been leased. At the time the old company worked the mine, none but very high-grade ore was shipped.

UTAH.

SAMPSON.—Reports show that on the 20th of June ten tons of first-class ore netted at Park City $1100, and 20 tons of second-class ore netted $800. Work on the new shaft is advancing rapidly under the contract. Owing to the large quantity of surface water, work had been retarded, but now it is pushed forward. The shaft has reached a depth of 75 feet, and is sinking at the rate of about 3 feet daily. No more shipments of ore will be made until the shaft is down 200 feet, as the expense of extraction will then be much reduced.

PATENTS GRANTED BY THE UNITED STATES PATENT-OFFICE.

GRANTED JUNE 5TH, 1883.

278,685. Tuyere for Blast-Furnaces. John H. Cremer, Chicago, Ill.
278,731. Manufacture of Charcoal. Henry M. Pierce, Grand Rapids, Mich.
278,737. Utilizing the Phosphorus and Iron of Forge-Cinder. Jacob Reese, Pittsburg, Pa.
278,738. Method of Dephosphorizing Metal by the Bessemer Process. Jacob Reese, Assignor to the Bessemer Steel Company (Limited), Philadelphia, Pa.
278,801. Rock-Breaker. Bertram F. Kramer, Charleston, S. C.
278,813. Draught Regulator for Locomotive and other Furnaces. Horace W. Norwood, Philadelphia, Pa., Assignor to the Norwood Spark Preventive and Smoke-Consuming Company, Camden, N. J.
278,816. Method of Producing Golden Sulphuret of Antimony. Charles E. Parsons, Assignor to the Brunswick Antimony Company, New Brunswick, Can.
278,859. Ore-Roasting Furnace. William Black, South Shields, and Thomas Larkin, East Jarrow, County of Durham, England.
278,861. Apparatus for Amalgamating Ores. Elias Bollinger, Louisville, Md.
278,889. Method of and Apparatus for Heating the Gaseous Fuel of Furnaces. John H. Cremer, Chicago, Ill.
279,032. Hand Drilling-Machine. George W. Smith, Boston, Mass.
279,089. Lining for Iron and Steel Furnaces. Edward L. Ford, Lyons, N. Y.
279,099. Apparatus for the Continuous Distillation, Sublimation, or Roasting of Solid Materials. Fritz Lürmann, Osnabrück, Germany.

GRANTED JUNE 12TH.

279,122. Gold-Washer. Charles S. Betts and Harry E. Wilson, Salt Lake City, Utah.
279,146. Stone Breaking and Crushing Machine. Philetus W. Gates, Chicago, Ill.
279,147. Stone Breaker and Crusher. Philetus W. Gates, Chicago, Ill.
279,157. Compound for Furnace-Linings and Fire-Brick. James Henderson, Bellefonte, Pa.
269,164. Ore-Concentrating Apparatus. Charles B. Hitchcock, Indianapolis, Ind.
279,264. Coal and Ore Carrier and Transmitter. Frank Murgatroyd, Cleveland, O.
279,319. Amalgamator. Abel H. Bliss, Chicago, Ill., Assignor of one half to Sylvanus L. Tripp, same place.
279,331. Steam-Boiler Setting and Furnace. Thomas R. Butman, Cleveland, O.
279,473. Manufacture of Steel by the Open-Hearth Process. William A. O. Wuth, Pittsburg, Pa.
279,503. Miner's Lamp. Edward K. Rollins, Scranton, Pa.

GRANTED JUNE 19TH.

279,519. Turbine Water-Wheel. Cornelius Barnhart, Walker Valley, N. Y.
279,596. Process of Obtaining Purified Iron in the Bessemer Basic Process. Jacob Reese, Pittsburg, Pa.
279,640. Dry-Ore Separator. Miles B. Dodge, San Francisco, Cal.
279,641. Separator for Wet Ores. Miles B. Dodge, San Francisco, Cal.
279,652. Device for Turning Fly-Wheels of Engines, etc. Patrick P. Kilcullen, St. Louis, Mo.
279,666. Radiator for Furnaces. Dwight S. Richardson, Brooklyn, N. Y.
279,679. Pumping-Engine. James Waters, Minneapolis, Minn.
279,761. Coal-Crushing Roller. John H. Hosie and James P. Hosie, Scranton, Pa.
279,788. Coal and Ore Carrier and Transmitter. Frank Murgatroyd, Cleveland, O.
279,796. Process of Coking Coal-Dust for Manufacturing Fuel Gas. James W. Pittinos, Philadelphia, Pa.
279,834. Drilling-Machine. James C. Smith, The Dalles, Oregon.
279,840. Retorting Amalgam. Carl A. Stetefeldt, New York City.

GRANTED JUNE 26TH.

279,947. Process of Purifying Iron by Means of Fluorides and Condensing the Gaseous Products therefrom. James Henderson, New York City, Assignor, by mesne assignments, to Charles G. Francklyn, same place.
279,962. Mining Tool. Thomas A. Mayes, Philipsburg, Pa.
279,969. Coal-Burning Furnace. Arthur G. Moore, Winton Place, and John W. Rahn, Cincinnati, O.
279,970. Chill for Metallurgic Furnaces. John Morrison, Pittsburg, Pa.
279,981. Turbine Water-Wheel. Joseph Raab, Dayton, O.
279,983. Ore-Crusher. William S. Sharpneck, Denver, Colo., Assignor of two thirds to H. N. Nichols, North Platte, Neb.
279,995. Amalgamator. Thomas Walker, Philadelphia, Pa.
280,001. Turbine. Abijah Woodward, Keene, N. H.
280,014. Coal-Elevator. Stephen V. Cook, Toledo, O.
289,027. Rotary Engine. Charles C. Garcelon and William A. Woods, Santa Cruz, Cal.
280,069. Amalgamator. Edward W. Nelson, Chicago, Ill., and Eugene H. Cowles, Cleveland, O.
280,093. Guide for Rolling-Mills. Alvan A. Simonds, Dayton, O.
280,102. Ore-Roasting Furnace. Thomas Walker and John F. Carter, Philadelphia, Pa., Assignors to said Walker.
280,133. Coal-Chute. Henry Claussen and Theodor Staeber, Ellinwood, Kan.
280,139. Tubing, Packing, and Operating Oil-Wells. Thomas L. Crowley, Rew, Pa.
280,158. Miner's Fuse. William Eltringham, Minersville, Pa.
280,248. Rolling-Mill. Thomas Shaffer, Phœnixville, Pa., Assignor to the Phœnix Iron Company, same place.
280,271. Brick-Drying Apparatus. Nathaniel S. Willet, Newark, N. J., Assignor to Minetta P. Cooper, same place.
280,284. Apparatus for Unloading Coal from Vessels. Walter S. Bogle, Chicago, Ill., Assignor of one half to Wendell R. King, same place.
280,310. Art of Manufacturing Iron and Steel. James Henderson, New York City, Assignor of one half to Charles G. Francklyn, same place.
280,316. Brick-Machine. Lewis B. Kennedy, Keokuk, Iowa.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, July 6.

The lack of interest attaching to the doings at the Mining Exchange has been aggravated this week by the absence of many who aid in framing the course of events there, and an unusually dull week has been added to the number of quiet ones which preceded it. The total number of mining shares sold at the Exchanges aggregates 69,815 shares, as against 138,740 shares last week.

There has been no news of any importance in regard to the Comstock mines, the prospecting-work at one or two particular points, from which so much is anticipated, not having as yet developed any thing, so far as the public is taken into confidence. California has dropped off further still, there having been sales as low as 10c. per share, while Consolidated Virginia has fluctuated between 35 and 45c. Sierra Nevada temporarily recovered to $4.15, but fell off again to $3.75, while Union sold at $4.75. Sutro Tunnel fairly held its own.

The Leadville stocks did not attract any special share of attention. It is stated, although we have been unable to confirm the report, that the Evening Star and Morning Star companies have again resumed dividends or propose to do so at an early date; $25,000 for each of them is the figure given. After eight months of suspension, this news will be received with interest, especially as it is understood to be the result of working a part of the large reserves of low-grade ore. Among the stocks dealt at the Exchange, Iron Silver holds its strong position at $2.90@$3, due to the confidence in the mine and its good business management. Amie and Chrysolite were quiet at their recent range, while there was little interest in Dunkin, Hibernia, Leadville, Little Chief, or Little Pittsburg. Climax has continued to gather strength, being carried up as high as 20c. on the 2d.

The Bodie stocks have been neglected almost completely.

Among the Tuscarora stocks, Navajo has again fallen back to $2.50, while all the rest have failed, in most instances, to record even a single sale.

In the miscellaneous list, Alice stands without a transaction. The mine is a steady producer, and should soon have wiped out its debt and have paid for improvements. Horn-Silver has fallen back a little, selling at $7. The outlook in the lead market, which, of course, largely affects the prosperity of this mine, is not considered good, and it is generally believed that a considerable stock of the metal is carried in Chicago. Green Mountain has been fairly active and steady. As yet, no decisive reports as to the developments in the tunnel have come to hand, though the time can not be far off when it must reach the Blake chute upon the continuance of which in depth the future of the mine chiefly depends. Robinson Consolidated has declined still further. Ontario has now safely passed through the spring deluge, and will soon obtain relief for its pumps by the completion of the tunnel. During the recent struggle with the water, the stock of ore at the mill was nearly exhausted. Sierra Grande has declined still further. Philadelphia is filled with sensational reports concerning the approaching exhaustion of this mine. The managers have made a very favorable contract with the Pueblo Smelting-Works for the working of the tailings, which were notoriously rich.

The daily newspapers are treated with protests from indignant stockholders of the Alta-Montana, and the errors of past managers are freely heaped upon the shoulders of the present officials. Professor Blake is understood to have made a somewhat rosy report on the mine. The trouble does not lie with the latter, but with the incapacity of those who put up the present plant, which can not handle the low-grade and refractory though cheaply mined ores. Nothing can save the company but a thorough remodeling of the metallurgical plant by one who understands his business. This will take considerable money.

Parnell seems to be going through the usual process of newly listed mines of being subjected to attacks.

DIVIDENDS.

The Evening Star Mining Company, of Colorado, has declared a dividend (No. 54) of $25,000 (as stated by Leadville papers).

The Morning Star Mining Company, of Colorado, has declared a dividend (No. 17) of twenty-five cents per share (as stated by Leadville papers).

The Rye Placer Mining Company, of Oregon, has declared a dividend of five per cent, payable July 16th.

The South Fork Gravel Mining Company, of California, has declared its first dividend.

The Standard Consolidated Mining Company, of California, has declared a dividend (No. 56) of twenty-five cents per share, payable July 12th.

PIPE LINE CERTIFICATES.

The activity which characterized the business at the petroleum exchanges at the close of last week, gave way to holiday dullness during the past few days of the present week, the market, however, showing more activity after the national holiday. Prices declined pretty uniformly and in the aggregate considerably. The monthly report, which is due on the tenth, is looked forward to with considerable interest.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

		Opening.	Highest.	Lowest.	Closing.	Sales.
June	30....	$1.18¼	$1.18¼	$1.16¼	$1.16¼	2,944,000
July	2....	1.16¼	1.16¾	1.15	1.15⅛	1,758,000
	3....	1.14⅝	1.15	1.14⅛	1.14⅝	1,546,000
	5....	1.14⅛	1.14¼	1.11⅞	1.12¾	4,812,000
	6....	1.13⅞	1.13⅞	1.11	1.12¼	1,504,000
Total sales.....						12,564,000

BULLION MARKET.

NEW YORK, Friday Evening, July 6.

The market is a little better than it was at the date of our previous posting; but it is, nevertheless, without any indications of value as to its early future.

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.
June 30	50 7-16	110¼	July 4	50½	Holiday.
July 2	50 7-16	110⅝	5	50½	110½
3	50 7-16	110⅝	6	50½	110½

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended July 6th, as compiled from various sources, amounted to $158,000, as against $138,500 reported for the previous week. The receipts from January 1st, 1883, to date are $5,988,213.53.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended June 30th	$215,178
Corresponding week last year	1,647,797
Since January 1st, 1883	6,620,882
Corresponding period last year	35,941,234

Imports.

Week ended June 30th	$48,492
Corresponding week last year	31,847
Since January 1st, 1883	6,940,957
Corresponding period last year	1,947,253

Foreign Bank Statements.—The governors of the Bank of England made no change in the bank's minimum rate for discount, and it remains at 4 per cent. During the week, the bank gained £172,000 bullion; but the proportion of its reserve to its liabilities was reduced from 41 5-16 to 35 3-16 per cent, against 35 per cent at the same date last year. July 5th, the bank gained £36,000 bullion on balance. The weekly statement of the Bank of France shows losses of 3,250,000 francs gold and 5,000,000 francs silver.

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14⅛ per cent, to arrive at actual value.

MINES.	States.	Month of May.	Year from Jan. 1st, 1883.

METALS.

NEW YORK, Friday Evening, July 6.

Copper.—As usual, after sales of large blocks to consumers, Lake copper has fallen into a state of quietude. Nobody wants to buy and there is very little offering, while the speculative interest has long since let the metal alone. We hear of only jobbing sales of Lake with 15½c. bid and 15¼c. held. In other brands, the market is quiet at the range of about 14@14½c., according to brand. There is again some inquiry from Europe, Baltimore being asked for this time. Abroad, the markets are fairly well maintained, a very encouraging feature for this metal. To-day's cables are £63 10s. for Chili Bars and £69@£69 10s. for Best Selected.

Tin.—The market is quiet and steady, the jobbing demand being good for the season. In a large way, we hear only of a sale of 100 tons at private terms. Quotations here are 21⅛@21⅜c. for spot Straits, Malacca, and Australian. England cables to-day to the Exchange, £93 5s.

Lead.—Though there has been some talk of a large transaction, the report is discredited, and no sales of any size are reported in any reliable quarter. The future of the market is looked forward to with some apprehension. Stocks here and in the West are undoubtedly accumulating, and the current demand is certainly not larger here than it was a year ago, while the output is still going on at a round rate. We quote nominally 4·40c. for Common and 4·42½@4·45c. for Refined.

Messrs. John Wahl & Co., of St. Louis, wire us as follows to-day:

Our market is firm Sales for the week sum up over 550 tons of Refined at 4·13c., and 190 tons of Common at 4·12½c.

Messrs. Everett & Post, of Chicago, telegraph:

The market remains the same, if any thing a shade weaker. Sales were 210 tons of Common at 4·15c., and 110 tons of Refined, a special brand, at 4·20c.

Spelter.—The market is extremely dull, in spite of the fact that among all metals this ore is apparently most favorably situated. Good ordinary domestic brands are freely offered here at 4·50c. England cables £15.

Antimony.—Nothing has been done. We quote Cookson's nominally 10⅝@10⅝c., and Hallett's 9⅝@9⅝c. for large lines.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, July 6.

American Pig.—The celebration of the national holiday has broken up the week and has restricted business to a small limit, though the interest has grown considerably. The diversion of business from a larger to a smaller number of furnaces is beginning to tell on the tonnage of those who have been able to meet present prices, which are, however, still so low that there is very little profit in the business. The feeling is decidedly better, and is now, too, beginning to affect No. 2 Foundry and Gray Forge. Other than standard brands of course are still selling at less than current quotations, but a greater desire is manifested to purchase, and it now looks as though bottom prices had been passed. Sales during the week have been small, and it will probably be some time before consumers come forward to anticipate fall demands. We quote No. 1, $21@$23.50 for good to choice grades, at tidewater; No. 2, $19@$20.50; and Gray Forge, $18@$19.50. Bessemer pig is dull, American being $20 at furnace, and Foreign $21 at tide, nominally. England cables 50s.@50s. 10d. Spiegeleisen is quiet at $31.50@$32 for 20 per cent, and $25.50@$26 for 10 to 12 per cent. The Passaic Zinc Company is building a furnace to make spiegel from zinc ore residue.

Scotch Pig.—As yet, the expectations of a growing business in Scotch Pig have not been realized. The arrivals this week were small. Freights are quoted 6s. per cable from Glasgow.

At the Exchange, the following cable quotations were received: Coltness, 60s.; Langloan, 59s. 6d.; Summerlee, 57s. 6d.; Gartsherrie, 57s.; Glengarnock, at Ardrossan, 54s. 6d.; and Eglinton, at Ardrossan, 48s. 6d. Warrants to-day were 46s. 11d. We quote here, all ex ship, Coltness, $23.50@$24; Langloan, $23.50; Summerlee, $23; Gartsherrie, $23@$23.50; Glengarnock, $22; and Eglinton, $20.50@$21.

Rails.—For summer and winter delivery, the majority of the mills can take no orders, except for small lots, and some of them are booked for the whole of the year. Nominal quotations are $38 at mill, but for winter and spring delivery, the mills accept $37 for round orders. England cables £4 15s.@£5.

Old Rails.—There are no features to note, the market being dull and lifeless at $21@$21.50 for Ts.

Scrap.—There are slight indications of an improvement. We quote $22@$22.50 ex ship.

Philadelphia. July 6.

The iron transactions of the past week have necessarily been restricted to very narrow limits. A review of the past month shows a slight improvement in foundry irons, and a good many inquiries for refined iron: but it remains to be seen whether this indication will be followed up by a more active demand. The general conditions surrounding the iron trade are unchanged, and there is but little inducement for buyers to depart from their accustomed policy. The great fact that stands before buyers is, that nothing but an extraordinary demand for iron can improve prices. Production is beyond requirements, and the only deduction from this is, that prices will be lower. On the other side, producers say that, while this logic is faultless, there is no room for a decline, either in crude or finished iron. Ever since the opening of the year, a conservative policy has been followed, buyers purchasing only for their most pressing wants and with very few exceptions, that policy has been strictly followed. Producers have taken fright, and restricted the output of crude iron. The result in the past few days is what sellers regard as an encouraging upward tendency in foundry irons. Very little will come of it during the summer. Intercourse with large consumers, both of

Full tables giving the total amount of dividends, capital, etc., will be printed the first week of each month. Dividend shares sold, 33,615. Non-dividend shares sold, 38,230.

forge and foundry irons, shows conclusively that an active demand will not be developed until September.

No. 1 Foundry is called firm at $21@$22. Standard and special brands have been bought pretty freely, but at lower prices than those quoted. Very little is selling at these figures, though efforts are made to create the impression that they are firm, and even like to advance.

During this month, the mills will be closed down for from two to three weeks, and those not well supplied with orders will remain out longer. Hence, forge iron will be dull, and as stocks are large, it is correct to infer that prices will remain weak, though some special brands are quoted with more firmness than for several weeks past.

Bessemer iron is nominally $21.50. Scotch iron continues dull and week. Some holders are endeavoring to unload stocks by concessions of 50 cents.

Merchant Iron.—Local trade is inactive, and card rates are 2·80c.; selling prices, 2·25@2·15c.; country mills, 2·10c. Common iron, 1·75@2c. Leading firms report stocks of iron light in consumers' hands, and therefore predict an improvement during August.

All kinds of construction iron have been selling pretty freely for a month or six weeks past, and leading manufacturers are satisfied with the prospects for the fall. An improvement is probable this month, as a good deal of business is generally held over from June, especially when prices are stiff as they have been.

Plate and Tank Iron.—The situation in plate could be much better; but notwithstanding low prices, a very large amount of business has been done in the aggregate. Capacity has been pretty well engaged all spring and summer. The chief cause of complaint is low prices. A few inquiries for large lots are on the market, and if buyers' terms are accepted, orders will be placed next week. There is nothing discouraging in the trade except low prices. Consumptive inquiries have been and are large, and will probably remain so, as bottom prices have been reached.

Sheet-Iron.—Mills are entering the second half of the year with well-filled order-books, and prices are firm at card rates for small lots as usual. Large consumers who look ahead for fall requirements in June and August will be favored.

Steel Rails.—Makers report the condition of trade to be satisfactory; though profits for the past six months have not come up to the returns of former seasons, owing to the low prices. Rates are $38. Light sections are $40.

Old Rails.—Offers for shipment are made at $22, with no takers. Yards are well filled with scrap, but little is moving.

Pittsburg. July 5.

Notwithstanding some very attractive concessions made by outside makers, consumers are purchasing only for immediate requirements, and are looking for a further weakness. Several mills have closed down for repairs. There will be a longer suspension for that purpose this year than is usual. Orders are scarce, and but little activity can be reported. Quotations for Foundry are $19@$21; Mill Irons, $17@$18. Concessions of 50 cents to $1 per ton have been made.

During the past six months, facilities for making iron have been considerably increased in and about this city. A large amount of plate iron could be sold, but the offers are below cost of making.

The output of pig-iron is fully up to all requirements, but stocks are light at Alleghany County furnaces. The present week is a dull one. Very little new business is under consideration, as manufacturers and buyers prefer to let the summer dullness pass away before entering into new or large contracts.

Less Muck Bar is offered, and quotations are $84. Merchant Bar is sold as low as 1·80@1·90c.

A few small transactions have taken place in wrought-iron pipes at 70 and 10 off. Sheet-iron continues in active demand for building purposes, and prices are as low as at any time for a year. A good many specifications are expected during July and August for construction iron for Western Pennsylvania delivery, but orders will not be placed except at exceedingly low prices. The Bessemer mills are working to full capacity. Offers have been received here at $37.50, fall delivery, but no sales have yet been made at that price. Old Rails are quoted at $23 for American.

The merchant steel trade is dull. Bessemer and open-hearth grades are cut. Crop-Ends are quoted at $25. Spikes, 2·60c. Selected Wrought Scrap, $24; No. 2, $23. Wrought Turnings, $16.

The Amalgamated Association holds its annual celebration in Philadelphia, August 7th.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, July 6.

Anthracite.

The influences which seem to be at work in attempting to shape the course of the coal trade are certainly not those of legitimate supply and demand. So far as the latter is concerned, even the most violent bull of coal stocks in Wall Street will not have the audacity to maintain that it is equal to that of last year. Our manufacturing industries in the New England States, always heavy consumers of anthracite coal, are not doing nearly as much work, our factories in such large cities as New York and Philadelphia are running on half time or less, the falling off in the production of iron is affecting the consumption of anthracite in the Schuylkill and Lehigh valleys; and yet, in spite of all this, the companies want to make themselves and the public believe that the market will warrant an advance in the price of coal, in spite of an increase in the production.

Middlemen have taken considerable coal at June prices, and there are indications even that they have ordered more than they will be able to handle.

Digitized by Google

The month will probably be consumed in attempts to market this coal among the few who may be made to believe in a prospective August advance, or who may be in urgent need of coal.

From Philadelphia come reports that are significant, and confirm the opinion expressed by us some time since. Mr. Gowen, of the Philadelphia & Reading Coal and Iron Company, it is said, has been distributing copies of an agreement for signature among the individual operators in the Shamokin District to sell the coal mined for Western shipment to him, instead of consigning it themselves. The details of this scheme have not as yet been divulged; but it is obvious that it will have its advantages for the individual shippers, and will contribute to that most important end, the cheapening of the cost of the coal in Western cities, by reducing the general expenses. It can not be expected, of course, that the individual operators should enter into such an arrangement without some hesitation; but it is believed that ultimately the majority of them will accept it.

Bituminous.

Except frequent reports of forced sales of coal at low prices, there are no features to note. Business is extremely dull. We quote Clearfield $3.75@$4, while Cumberland is entirely nominal at $4.10@$4.35.

STATISTICS OF COAL PRODUCTION.

Comparative statement of the production of anthracite coal for the week ended June 30th and year from January 1st:

TONS OF 2240 LBS.	1883.		1882.

Horsford's Acid Phosphate

Makes a Cooling Drink.

Into half a tumbler of ice water put a tea-spoonful of Acid Phosphate; add sugar to the taste.

WANTED.—A COPY OF TREATISE ON Ore-Deposits, by Bernard von Cotta, translated by Frederick Prime, Jr., new or second-hand. Address, giving price, E. W. F., P.O. Box 1833, New York.

MAPS.

IDAHO.—The Wood River Region of Central Idaho, giving the first correct Geography of that recently explored and remarkable Belt of Discoveries of Gold and Silver Mines on the tributary streams of the WOOD and LITTLE WOOD Rivers, on the Upper Waters of the SALMON RIVER, among the SAWTOOTH MOUNTAINS, and on the Forks of the BOISE RIVER; embracing the Mount Estes and Custer Mines on the north and the Oregon Short Line Railroad on the south. Prepared by Frank J. Scott. Scale, 5 miles to the inch. Size, 15 x 26 inches. In paper pocket Price, $1.

MEXICO.—Map of Mexico. Showing Railroads, Broad Gauge and Narrow-Gauge, Constructed; and Railroads, Broad-Gauge and Narrow-Gauge, Proposed. This very large and finely-engraved Map, constructed originally by the government for official purposes, contains all the information obtainable by it, and shows minutely the towns and villages of the entire country. Scale: 26·6 Mexican Leagues to the degree, and 69·16 English Miles to the degree; also, Kilometrical Scale. 1881. Size, 53x41 inches. Printed in colors. Pocket form, $5.

MAP OF MINING CLAIMS ADJOINING LEADVILLE, California Mining District, Lake County, Colo. By Edward Rollandet. 1879. Mounted on muslin, $2.50. In cloth-bound covers, $2.

MINING MAP OF UTAH.—Showing the location of the Mining Districts, over an extent of territory 150 miles from North to South. Compiled from U. S. Government Surveys and other authentic sources. Scale, one inch to four miles. Colored. 1879. Pocket form. $1.50.

NEW SECTIONAL AND MINERAL MAP OF UTAH.—Pocket form. Compiled from the latest U. S. Government Surveys and other authentic sources, exhibiting the Sections, Fractional Sections, Counties, Cities, Towns, Settlements, MINING DISTRICTS, Railroads, and other internal improvements. Scale, one inch to eight miles. Colored, 1878. $3.50.

POCKET MINING ATLAS OF THE MINES OF THE UNITED STATES.—Showing the Mines of NEVADA: the Comstock Lode, the Eureka, Treasure Hill, and Tuscarora Districts; CALIFORNIA, including Map of the Bodie District; COLORADO, including the Leadville, Silver Cliff, San Juan, Caribou, and Central City Districts; DAKOTA, including Map of Deadwood; MONTANA, IDAHO, UTAH, ARIZONA, NEW MEXICO, LAKE SUPERIOR REGION, the SOUTHERN STATES. 1880. Printed in colors, and bound in flexible leather covers. Price, $1.

IN an inaugural address delivered at the opening of the Rose Polytechnic Institute of Terre Haute, Ind., in March last, President CHARLES O. THOMPSON, formerly of the Worcester Free Institute, outlined the scope and defined the aims of the school to the development of which he is now lending his best efforts. We notice, as a commendable and significant departure from the usual course in civil engineering, that the young men who propose to be civil engineers will spend a part of their time in the machine-shop, that practice time to be concentrated in the first of the four years' course. Mr. THOMPSON'S address will be read with much interest by all those who follow developments in the great and promising field of technical education.

MR. JOHN R. MCCUNE, the umpire chosen by the Railroad Coal Trade Tribunal, has decided the question pending between the railroad coal operators and their men, whether 3 or 3½ cents were to be paid per bushel of 76 pounds for mining for all coal running over a one and a half inch screen. He has fixed the price at 3½ cents, thus offering a fair compromise, which probably would not have been reached except after a protracted struggle. His reasons are certainly convincing. While acknowledging that there is little profit in mining in the present overcrowded state notably of the lake markets, he urges that some saving might be made by operators in the expenditures for dead-work, royalty, and car service, thus enabling them to meet the men half-way. The latter, on the other hand, are told that they are mistaken when they assert that the cost of living now is as great as when the price of mining was four cents. Mr. MCCUNE'S statement is forcible; it is that of a clear-headed, impartial business man, who has looked the issue squarely in the face, and advises both parties, for their common good, to yield to the hard logic of facts. It is a question which Pittsburg operators will not unnaturally ask themselves, whether they must not be content to give up a large share of the lake trade for good, unless they can establish by undeniable evidence, not alone that their coal is better than that of their younger rivals, but place it before their customers in dollars and cents.

FROM England comes news that ought to be gratifying to those of our Western copper producers who sell argentiferous copper ores and mattes in the English market. We understand that recent contracts made there show better prices, equivalent to about 13 cents for the copper in the ore or matte. This, we understand, is due to the fact that a little "ring," as we should call it in this country, among the three smelting-works which controlled the working of this class of material, is threatened with competition. A firm near Liverpool has recently commenced working, and it is stated that the building of another large works is contemplated.

As for those producers who ship ordinary refined copper or black copper, the course of the London market during the past six months has been fairly encouraging. It is generally understood in England that one firm has been persistently bulling the market, and from a statistical point of view the market is in a fair condition. Messrs. JAMES & SHAKSPEARE, of London, furnish the following figures for the first six months of the year :

		January 1 to June 30. 1883.	1882.	1881.
Imports	Chili	20,583	20,388	17,337
	Other foreign	21,381	16,580	18,250
Tons		41,963*	36,968	35,587
Deliveries	Chili	19,799	21,606	21,323
	Other foreign	21,138	16,779	14,868
Tons		40,937	38,385	36,191

According to the same authority, the visible supply on the 30th of June was 48,197 tons at the close of last month, against 46,587 tons on the 31st of December, 1882, and 47,401 tons on the 30th of June, 1882. The Board of Trade returns are not yet at hand to show how the arrivals were distributed. So far, there are no features in the situation in London or here to warrant any uneasiness, while a revival of business activity may easily be attended by a higher range of values on both sides of the Atlantic.

"WHAT IS A KNOWN LODE?"

Section 2333 of the U. S. Revised Statutes provides that

"Where a vein or lode, such as is described in section 2320 (that is, a vein or lode of quartz or other rock in place, bearing gold, silver, cinnabar, lead, tin, copper, or other valuable deposits), is known to exist within the boundaries of a placer-claim, an application for a patent for such placer-claim which does not include an application for the vein or lode-claim shall be construed as a conclusive declaration that the claimant of the placer-claim has no right of possession of the vein or lode-claim ; but where the existence of a vein or lode in a placer-claim is not known, a patent for the placer-claim shall convey all valuable mineral and other deposits within the boundaries thereof."

Under this provision, the Iron Silver Mining Company at Leadville, Colo., brought suit against certain parties working lode-claims upon the (patented) Wells & Moyer placer-claim belonging to that company. A clause in the placer patent excepts from the grant thereof all lodes known to exist within the claim at the date of the application. It seems to have been admitted that no lode had in fact been *located* prior to that date ; but the defendants contended that it was generally known that a lode or vein of rock in place existed within the placer-claim before the application for a patent ; that shafts and other developments before made in lode-claims adjoining the placer established the fact that a vein or lode extended underneath the placer-claim. From this, they argued that it was a "known lode' within section 2333, was excepted from the grant in the patent, and they had the legal right to go upon the surface of the placer, after patented, and sink shafts and locate and hold portions of this vein.

In the United States Court at Denver, Judge MCCRARY held, upon these pleadings (in the case of the Iron Silver Mining Company *vs.* Sullivan *et al.*), that the term "known lode or vein" within section 2333, which was reserved out of the placer patent grant, meant a known lode or vein mining claim, which had been duly located or recorded and owned by some third party before the application was made for the placer patent ; and as it appeared by the defendants' answers that they did not locate or discover their lode-claims till after the placer patent was applied for or had issued, their rights were not reserved or excepted in the placer patent, and they were trespassers on the patented ground of the plaintiff company.

This decision applies to several cases. It is reported that one of them,

Digitized by Google

as a test case, will be carried up to the Supreme Court. The above statement of the point involved is taken from an intelligent and apparently accurate summary in a Denver journal. Assuming it to be correct, we do not see how the Supreme Court can refuse to confirm this decision. There may be circumstances that would justify the conclusion that a lode is known to exist before it has been duly located. We can imagine, for instance, that an explorer might find and fully expose a lode, and that, by a sharp race or a clever trick, some one might cover it on the record-book with a placer-claim, just before he got it recorded. But no such circumstances exist in this case. The "lode" here is the "contact" or ore-bearing zone of Leadville; and it was simply inferred or presumed, not known, to exist under the placer-claim. As a matter of fact, in numerous instances, placers do cover the outcrops of the lodes that formed them. "Deposits of *débris* in place" is the name given to such placers, and a striking example is furnished by the great gold mine known as El Callao, in Venezuela, of which a brief account, from an excellent authority, is given in another part of this issue of the JOURNAL. But something more than this possibility or even probability should be required to constitute a "known lode."

The case above mentioned is important and noteworthy in several particulars. It is one of the few victories won by the Iron Silver Mining Company out of much litigation. The lode-locations, made with much patient care and at great expense, by Mr. WILLIAM A. STEVENS, and afterward acquired by this company, have been repeatedly curtailed of the privileges which the law was intended to confer, by the hostile verdicts of Colorado juries, who seemed determined that, law or no law, there should be no "going beyond side-lines," if they could prevent it. Now the placer-claims came into court, and in this case with better luck. This decision gives to the company an area of 160 acres in California Gulch and on Printer Boy and Iron hills, under a large part of which the "carbonate contact" is supposed to extend. Within this area, no lode-claims are recognized, if not "known" before the application for the placer patent. A large number of later lode-locations are thus ruled out. Among them are said (we do not know with what accuracy) to be the Brooklyn, Eighty-One, Sligo, General Sherman, Rebel, Minnie, Minnehaha, Gray Eagle, Gardiner, Goodell, and Arctic.

This decision, if sustained, opens a curious suggestion to miners. Since the law does not require that placer-claims shall contain placers, but declares that they may include "all forms of deposit excepting veins of quartz or other rock in place;" and since it provides that a placer-claim not containing "known" lodes shall cover "all valuable mineral and other deposits within the boundaries thereof," it is only necessary for a miner who has discovered "float" in a new locality to avoid looking for any lode, and to locate a placer-claim and make application for patent at once, in order to obtain 160 acres of complete and indefeasible mining rights. The cost per acre will be but $2.50, against $5 for a lode-claim; and the limitation of the side-lines may well be submitted to, in view of the large area. It appears, therefore, that for any one who likes that sort of title, the "square location" is already given by law, even on quartz-claims, and in dimensions exceeding all that has been heretofore proposed. We shall not be surprised to see shrewd operators taking advantage of this fact; and the result will be a good deal of fighting. *

THE TRANSMISSION OF POWER BY ELECTRICITY IN MINES.

The exigencies of special circumstances in the use of power in mines are often so peculiar that necessity forces engineers to adopt methods which above ground might be considered unwise. Work in inaccessible localities, danger of fire, inefficiency of ventilation, often make the carriage of steam through long lines of pipe practically impossible, and therefore hydraulic power, and more frequently still, compressed air, have found more frequent applications than above ground. A valuable addition to the number of methods of transmitting power over long distances has, of course, been hailed by mining engineers with much satisfaction, and they were among the first to turn transmission by electricity to account. Some time since, we submitted data gathered by work in a number of French mines, and through the publication of results by B. R. FÖRSTER, manager of the Royal Saxon collieries, we are in a position to add some details as to the experience gathered there.

Herr FÖRSTER has applied the electric transmission of power to two widely different cases. In the one, it was necessary to secure ventilation for the headings in a colliery at Zankeroda. The plant consists of a Dolguruki rotary engine, running at a speed of 800 revolutions, directly coupled to a Siemens & Halske dynamo machine placed at a distance of 367·5 feet from the shaft. The conductor, a copper rod 0·275 inch in diameter, is carried down the shaft to a depth of 856·3 feet, and from there to the fan, 1335·4 feet, a total distance of 2559·2 feet. The second machine, of the same type, mounted in the mine, is connected with the fan by belting, the fan being of the well-known Schiele type, with a 3·2-foot wheel, capable, according to the statements of the builders, of furnishing, at a speed of 500 revolutions, 6363 cubic feet of air at a pressure of 0·79 inch, and at an expenditure of power of 1⅞ horse-power. A series of tests were conducted above ground, with the whole plant complete, but with a length of conductor of only 160 feet. It was found that the engine delivered to the dynamo-electric machine producing the current 2·56 horse-power, of which 1·4 horse-power was converted into work in the receiving dynamo-electric machine, thus showing an efficiency, with a circuit of 160 feet, of 54·3 per cent. The dynamo was then running at a speed of 481 revolutions, which was reduced to 448 revolutions when the plant was in full operation, so that the efficiency of the transmission was reduced by 3·9 per cent in addition, thus carrying it down to very nearly 50 per cent. The fan, when the driving dynamo was running at 800 revolutions, was making 361 revolutions per minute, delivering 7000 cubic feet into the air. The cost of the entire plant was low, and it is reported to have worked efficiently for many months since its construction.

The second case of a successful application of the transmission of power by electricity is quoted by Herr FÖRSTER, who arranged the electric railroad in one of the main cross-cuts of the Oppel colliery at Zankeroda. The cross-cut is 2362 feet long, and is the outlet for the coal mined in the vein, the quantity delivered to it being 600 mine cars per day of 16 hours, each car containing 1047 pounds of coal, and weighing loaded 1594 pounds. We can not enter into details of the construction of the plant. It resembles in many points the design generally adopted by SIEMENS. In practice, a train of fifteen cars is moved at a speed of from 7·4 to 9·8 feet a second, the steam-engine at the mouth of the shaft making from 225 to 250 revolutions during the run, lasting from 3½ to 4½ minutes, through the 2034 feet of cross-cut. When the steam-engine was doing this amount of work, it delivered, according to brake trials made, 11·2 horse-power. The locomotive was at the same time developing 4·18 horse-power, or, assuming the friction of the gearing of the locomotive to have occasioned a loss of 25 per cent, the power actually transmitted by the electric current to the locomotive was 5·22 horse-power, or 46·6 per cent. The consumption of steam, with a pressure of 65 pounds, is estimated at 45·6 cubic feet per round trip of 15 cars. Herr FÖRSTER gives a statement of cost in which he shows that, making an allowance of 15 per cent of the cost of plant annually for wear and tear and sinking fund, it costs per car of coal hauled 3·01 pfennige with the electric road, 3·71 pfennige with horses, and 6·2 with men, when hauling 660 cars per day. When the capacity is increased to 800 cars per day, the cost for the electric road is reduced to 2·70 pfennige, while the others are not sensibly affected.

These two examples, we believe, furnish ample proof of the fact that there are probably many cases in which the transmission of power by electricity would pay well, notwithstanding the fact that the loss may be roughly placed at 50 per cent for moderate distances. This is particularly so where fuel is cheap, or where high heads of water are available, as in many of our mining districts, so that turbines running at a high speed can be used to drive the dynamo machines. There is only one point in connection with the electric railroad which needs attention. It seems difficult and dangerous to stop the trains suddenly, so that the engineer has not that absolute control over the locomotive which is desirable, even in underground roads.

CORRESPONDENCE.

Working Gold Ores in Georgia.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: For one and a half years, I have been experimenting with the "Dr. Charles process" for working sulphuret ores in these mines, with the results given below. Although the mine shows a great abundance of $10 ore, it is of so refractory a character that, for the last twenty-five years, all attempts to work it have resulted in failures.

The Charles process, as originally planned by him, included heavy and costly machinery, requiring great power to drive it. The result was all that the inventor promised, and of course entirely satisfactory; but the means of reaching it were entirely too slow and quite unsatisfactory. By carefully watching the process from beginning to end, and throwing out first one and then another part of the heavy machinery, I found it all to be useless, and worse than useless, except the concentrator.

The secret was all in his method of preparing the mercury. To make sure of this, other prepared mercury was tried, then chemically pure mercury, and the greatest care taken to get the most favorable flow of water over the plates, and the best adjustment of them. Our stamps are 750 pounds each, and I find by careful experiment that a 7-inch drop, 50 drops per minute, gives the best result. Our ore is much harder than the Lumpkin County ores, requiring heavier stamps. The exact amount of ore run through ten stamps in twenty-four hours I can not tell; but the amount of gold made will average fourteen dollars to the stamp every twenty-four hours. Every thing taken from the mine is run through the mill and counted as ore. The tests were in three runs of ninety-six hours each; the ore taken equally, as nearly as possible, from the different parts of the mine; and the three runs averaged, each in the clean-up, 14,000 grains gold 965 fine. The runs with chemically pure mercury and that prepared in the ordinary way, from exactly the same ore, gave less than one third.

The process is not patented, and the extra cost of using it is about five

Digitized by Google

cents per ton. The total cost of milling and separating our ore is about fifty cents per ton, or about double what it costs in Lumpkin County.

There are very extensive mining properties in this vicinity, developed and undeveloped, that will pay from $3.50 to $10 per ton in the mill worked by this process, some of them showing immense amounts of low-grade ($3.50) ore above water-level, with water-power to run 300 heavy stamps. Such a mill would earn about $30,000 a month, and cost about $150,000 to build, with all modern improvements.

A start has been made to build a 160-stamp mill on one of these mines, to run by water-power. A wire-rope tramway will carry the ore from the main working-shaft to the mill, a distance of 1200 feet, with a fall of 12 degrees. A drain and cross-cut tunnel, about 1500 feet in length, cuts one vein 15 feet thick, two 8 feet thick each, and some smaller ones, 150 feet below the surface. The values of these ores are not given from assays, but from actual working in our common stamp-mills, in 100-ton lots, and will be repeated to satisfy any responsible parties who may wish to make such a test of Georgia ores. To such parties, this company's mines and mills are at any and all times open for inspection. No charge will be made for working 100 or more tons of ore from any of the mines, and the very closest scrutiny is invited. This company has no interest in other mines in the South, and no property for sale; but does this to satisfy those people who are afraid of mining property here, and yet are desirous of investing money in this line. A. H. MOORE.

OPHIR, CHEROKEE CO., GA., May 24.

A Reply to Mr. Arents.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: In answer to the reply of Mr. Arents, in your issue of July 7th, I wish to say only a few words in regard to the experiment at the Northern Belle mill. It is hardly possible to make a reliable test by roasting one ton of the ore in a Stetefeldt furnace of large capacity. Mr. Belding does not state how he obtained "loss in roasting, 5 per cent of weight and 9 per cent of value." Nor is it entirely clear to me what he means. In fact, to determine a loss of silver in roasting by the ordinary method is impossible in this case. The roasted ore is spread over such a large area that it is not practicable to collect it all. And if this were done, the product would not represent the original ore. Large quantities of roasted ore cling to the walls of the furnace and dust-chamber, and drop down constantly. Besides this, I wish to say that Mount Cory ore, resembling in its mineralogical character very much the Ontario ore, needs a different treatment from Northern Belle ore, to obtain high chlorinations. The Northern Belle ore is not "banked up," but cooled shortly after discharging. If a larger quantity of Mount Cory ore, say 10 tons, as Mr. Arents himself suggested, had been put through the furnace, and kept on the cooling-floor for twelve hours, as is done at the Ontario mill, the chlorination of the silver would have increased materially, and the loss in tailings would have been, most likely, 5 or 6 per cent, in place of 14 per cent. Mr. Belding himself is fully aware of this in stating that more experience in treating this ore would improve results materially.

NEW YORK, July 10. C. A. STETEFELDT.

Mechanical Roasting-Furnaces.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: In your issue of June 30th, I notice a long communication from Mr. C. A. Stetefeldt, criticising the remarks on "Mechanical Roasting-Furnaces," which appeared in the paper I read before the Institute of Mining Engineers at the Roanoke Meeting. In his anxiety to make known the special merits of the Stetefeldt furnace, he has rather unfairly quoted sentences from my paper, which, standing alone, without the sentences which follow them, give an entirely different meaning to that which is really expressed. The quotation he bases his remarks on is the following: "Like all mechanical roasters, however, this furnace can not be relied on for perfectly uniform results; and until this and other mechanical difficulties have been obviated, I have fallen back on the old-fashioned but always reliable Fortschaufelungs furnace." Here he stops his quotations, evidently because the following sentences, explaining the reasons for the adoption at this particular mine of the reverberatory furnace, are plainly set forth, and would appear, I believe, rational to most mining engineers. This sentence which he omits is: "Here, in the South, where labor is obtainable at 90 cents per day, where wood costs us less than $1 per cord, delivered at the furnace, the advantages to be gained by automatic rabbling, in whatever way obtained, are so slight that they are much more than counterbalanced by the perfect control one has all the time over the charge roasted in the reverberatory furnace. The advantages of the latter in the matter of first cost are, of course, undeniable." As this latter sentence shows, I am by no means advocating a general abandonment of the mechanical roasters for reverberatories, but merely point out the fact that there are still places where the latter can be economically and advantageously adopted. I fully agree with Mr. Stetefeldt in his remarks, that "of all engineers, the members of the American Institute should be progressive and well informed;" but my idea of a progressive and well-informed engineer is one who, by reason of his experience and observation, is able to obtain the best average results with the most economical outlay of capital. It does not follow that, because under certain circumstances one metallurgical appliance proves better than another, it would also prove so under diametrically opposite conditions. Mr. Stetefeldt, in warning all engineers from following such an example as mine, seems to assume that reverberatory furnaces, because they have proved themselves successful for one hundred years, should now, under all circumstances, be abandoned for other furnaces, whether the conditions which called forth the invention of the mechanical furnaces prevail or not. As a fact, Mr. Stetefeldt is probably aware that to-day, except where labor and fuel are exceptionally high, the reverberatory furnace, for roasting ores, is the one most generally in use; and that it has attained the venerable age of over one hundred years, is certain proof of its adaptability to the uses it is put to. Farther on, Mr. Stetefeldt, as a proof of the non-reliability of results from this class of furnace, quotes the fact that, in zinc-blende roasting, "the roasters are fined if they leave too much sulphur in the charge." He forgets to add, though, that as a general rule, these men work by the ton, and naturally endeavor to push the yield of the furnace beyond its natural capacity. In fact, this is one of the advantages of this class of furnace that, while practically giving a continuous process, each individual charge is under the perfect control of the operator. The example quoted by Mr. Stetefeldt of the operations at the Manhattan mill scarcely bears on the subject, as the conditions there are totally different from what they are down South. In regard to the "Brückner" furnace mentioned, Mr. Stetefeldt, as well as every other engineer who has had experience with it, will agree that it does splendid work when in the hands of thoroughly experienced men; but no one, I fancy, would assert that the results are generally better than those obtained in a well-managed reverberatory, and certainly the first cost is very much higher.

Now, in regard to the Stetefeldt furnace itself, probably few engineers besides Mr. Stetefeldt have greater belief in its many advantages, especially for chloridizing roasts, than myself. Its excessive cost, however, very naturally prevents its general adoption except by very wealthy companies. Further, I do not think that so far it has been introduced for roasting sulphides of iron sufficiently to prove all of Mr. Stetefeldt's claims for it. We all know that the combustion of sulphur is a very slow process. It requires not only the presence of a very large surplus of oxygen, but also requires considerable *time*, and as the amount of sulphur in each charge is liable to vary very materially, it stands to reason that the best furnace (all other considerations being equal) is the one where the ore can be subjected at will to a longer or shorter exposure to the oxidizing medium, as may be necessary. In this respect, the rotary furnaces would seem to have considerable advantage over the shaft furnaces. Now, one word more in regard to the relative cost of the two furnaces, on which Mr. Stetefeldt lays so much stress, and it will be apparent that circumstances may occur where, if a mining engineer has any regard to the pockets of his stockholders, it is better for him to adopt, provisionally at least, appliances a hundred years old rather than newer inventions of a more expensive type. The actual cost of one forty-foot reverberatory furnace was, according to the company's books, $760. This was exclusive of the chimney, which was already built some time ago. The cost of roasting, quoted at $1.10, fully includes all incidental expenses and allowances for wear and tear, the actual cost of roasting being 86½ cents per ton. Now, Mr. Stetefeldt, basing his figures on 24 tons per day, puts the cost of roasting at 59½ cents per ton, or, in round figures, one half our present cost, and from this deduces that an annual saving would be effected of $3636 by the use of his furnace. He further admits that these figures, under a less production, would be materially changed Now, as a fact, our present production of concentrates is under ten tons per day, so that, taking him at his own figures, if I had put up one of his furnaces, the cost of roasting would not have differed much from our present cost, and our stockholders would have been out of pocket to the tune of $9740, for no apparently corresponding benefit, except to the Stetefeldt Furnace Company. I can assure Mr. Stetefeldt that the whole matter was very carefully considered before such a retrogressive step in engineering practice was taken, as he calls it, by the erection of an appliance having one hundred years' record of good results.

As soon as Mr. Stetefeldt can get some more progressive engineers having the same conditions applying as with us to put up one of his $10,500 furnaces, and prove to us by a six months' run the claims now set forth by him, I can assure him I shall not prove too old-fogyish to consign our present furnace to an honorable oblivion, and at once erect one of his stately structures in its stead. E. GYBBON SPILSBURY.

NEW YORK, July 11.

EL CALLAO MINE OF VENEZUELA.

Special Correspondence of the Engineering and Mining Journal.

This mine is situated in Venezuelan Guayana, on the drainage of the Essequibo River, about 130 miles from the Orinoco River, and 250 miles from the Atlantic Ocean.

The lode is of sugary white quartz, about 5½ feet in thickness, with a pay-chute of ore from 600 to 700 feet in width; the lode has an average dip of 42 degrees; the greatest depth attained is 490 feet.

The mine is situate in a low valley, and the vein was discovered by placer workings from the surface down some 60 or 80 feet in depth, to a point where the vein became solid. No record was kept of the placer gold thus obtained; probably fully $2,500,000 were taken out from 1856 to 1870, when the lode proper was reached. From 1871 to May 15th, 1883, 144,265 tons of ore have been mined and milled, yielding 533,860 ounces of gold, 916⅔ fine, or an average of 3·7 ounces per ton.

The ore is crushed by American stamps; the gold is saved by amalgamation in the batteries and on short copper plates. The sulphurets, amounting to from one half to one per cent and of high value, have practically never been utilized. With proper concentration-works, the ore would probably have shown a gross yield of fully 4½ standard ounces per ton.

For the first six months of 1883, about 12,000 tons of quartz have been crushed, yielding nearly 61,000 standard ounces of gold, or over 5 ounces per ton.

El Callao is by far the richest free gold quartz mine the writer has ever seen, and is probably unexampled in the history of gold mining.

S.

WASHING GOLD IN PERU.—A correspondent sends *Iron* the following account, describing how the Peruvians did, and perhaps do, successfully operate: "The whole of the Chucamba (Peru), for a number of leagues above and below the Temple of the Sun, is auriferous, and the inhabitants of the province of Huamelies, through which it passes, obtain, by washing the sand and by means of sheepskins, $200,000 or $300,000 worth of gold annually. The wool on the skin is cut out until it is about half an inch in length. The skins are then anchored down, with the wool side up, by means of loose stones placed on them, in and below the various rapids, in which position they are suffered to remain from six to twenty-four hours. They are then carefully raised out of the water, turned wool side downward into a batea (tub) of water, and thoroughly washed; the gold falling from the wool of the skin is finally collected from the bottom of the batea. Sheep were unknown to the Incas, and as they had obtained an immense amount of gold from this Pactolean stream, it is presumed that they used the skins of the llama and those of the vicuña.

OFFICIAL STATEMENTS AND REPORTS.

THE CERALVO MINING AND BENEFICIATING SYNDICATE, CERALVO, MEXICO.

Mr. Richard E. Chism, a mining engineer who is known to have had experience in Mexico, has recently reported on the mines belonging to Mr. F. P. Thompson, of Monterey, in the Ceralvo District, Nuevo Leon, Mexico. Mr. Chism describes the main geological feature of the district as massive limestone, in which most of the ore-deposits outcrop. Mr. Chism notes in detail the developments, the character of the veins, and the extent of the reserves in the Guadalupe, Mina del Agua, Refugio, Colorado, and Valenciana mines. The ores are calcareous and ferruginous mixtures of galena and blende, with considerable quantities of copper in some instances, and varying amounts of silver. Mr. Chism estimates that the Guadalupe has $62,000 profit in sight, the Mina del Agua $51,000, the Refugio $27,000, the Colorado $256,000, and the Valenciana $30,000. We are not in a position to critically examine these figures, which Mr. Chism seems to have compiled with an evident desire to be on the safe side, so far as a calculation of the quantities of ore available is concerned. He has, however, decidedly over-estimated its money value, so far as the lead is concerned, and we believe that he is not under any circumstances justified in looking to the utilization of his zinc-blende with a profit. It is simply preposterous to expect to work zinc-blende in an out-of-the-way place in Mexico for three cents a pound. We would advise those who own the mines to deposit their blende on the dump for the present, and consider its presence in the ore rather as a very serious drawback than as a possible source of revenue.

STEEL versus IRON FOR MACHINERY PURPOSES.

In the course of a discussion before the German Society of Engineers at Aix-la-Chapelle, Herr André gave the following instances of the failure of steel to take the place of iron, notably for heavy machinery:

Two years ago, we replaced the iron shaft of a high-speed steam-engine by a Bessemer steel one, manufactured at works which for such articles stand almost, if not quite, equal to Krupp and Bochum. After two years' work, the shaft broke suddenly when moving very slowly, and without any load attached (the train of rolls was not coupled). We were about to replace it with another Bessemer shaft of mild steel, when the manager of the steel-works himself advised us to return to the old material if there was any risk of the shaft becoming occasionally heated while working; for, he said, strong cooling appliances were then brought at once to bear on the shaft, which produced microscopic cracks on the surface, and these, in a short time, might produce an unexpected breakage. In order to confirm this, he (the speaker) telegraphed to ten wire-works where similar engines were in use, and found that the majority employed and preferred iron. It appears, therefore, that iron shafts are again replacing the steel ones which had superseded them for quick and heavy work, where there is any risk of heating. This was further confirmed by the foreman of engine-works on the Rhine, who stated that in two years they had had five breakages of heavy steel shafts, and had in each case replaced them with iron. In one of these steel shafts, of 15·75 inches diameter, a hole as large as the fist was found, and in it were two small steel balls, which had ground themselves quite round and smooth in the two years. As mild steel is even more inclined to form bubbles than hard, it seems to be, at present, even less adapted for heavy shafts and pieces.

It appeared to be as little adapted for steam-boilers. The same engineer, for example, had informed him that a boiler he had constructed cracked right across the bottom when removed from the workshop to the survey-yard, although great care had been taken in riveting and drilling the holes.

The constructor should remember also that "mild steel" is a very vague term; and it is necessary to ascertain where and by what process it is made. Nothing can be determined by the amount of carbon it contains; for, although one can estimate approximately, according to the carbon contained, the materials produced by a certain process at certain works, it is impossible to compare the productions of different works, especially where different processes are adopted. For example, Thomas steel, containing from 1 to 1·5 of carbon, may be exceedingly soft, while Bessemer steel, containing the same amount, may be so hard that a knob occurring on a thin wire rod can hardly be rolled away.

The differences in Thomas steel itself are very great, and although Mr. André could speak very favorably of it from personal experience, there were many complaints of inequalities. If an engineer, therefore, resolves to have no mild steel, but only ingot iron, he will find the border line between the two so confused that the following definition may be looked upon as a necessary expedient, "No material capable of considerable hardening shall be called iron," and, if narrowly examined, it will be seen that a great deal of the ingot iron specified as "incapable of considerable hardening," is, nevertheless, capable of very considerable hardening under certain circumstances, such as a sudden cooling of a heated shaft. This "inconsiderable hardening" is just sufficient to shrink the surface, produce tension, small cracks, and finally breakages.

Herr Petersen supplemented the remarks of the preceding speaker, stating that it is well known that various difficulties occur in casting thick steel ingots, and it is even more frequent to have a porous casting in mild than in hard steel. If steel ingots have incomplete, hollow, or porous spots, these do not become welded together by further heating and working, but, after being rolled thin, they retain their porosity, as unwelded spots are retained in wrought-iron. As these porous places are generally in the center of the ingot, the round bars, piston-rods, and axles made of it have also usually an internal weakness, which it is difficult to set right in the working, and which may cause breakages in the future. Thus the plunger-rod of a subterranean pumping-engine, on being tested with water up to 20 atmospheres, was shown to be hollow in its whole length, and water burst out of the cleft at the end of the rod. The following accident with the piston-rod of a pumping-engine occurred at a Westphalian coal-pit. The piston-rod in question belonged to a single-acting Cornish beam engine, with a cylinder diameter of 6·56 feet, and a stroke of 13·12 feet. The effective steam pressure was 4·5 atmospheres, the vacuum about 23·6 inches, so that the net effective pressure on the piston was 5·3 atmospheres, amounting altogether to 160 tons. The diameter of the piston-rod was 9·84 inches. The break occurred at the beginning of the descent, so that 11·5 feet of the stroke had yet to be accomplished. Falling from this hight, the piston struck the bottom of the cylinder and smashed with it the valve-boxes and all the principal parts of the engine. The breaking strain of the piston amounted in the full transverse section only to about 2·2 tons per square inch, and in the hollow place to about 9·8 tons per square inch. A lead casting the size of the fist was taken out of this hole. These examples are not meant to detract from the valuable qualities of cast steel, but merely to point out those weaknesses in it which must be guarded against in practice.

ECONOMY BY SUBDIVISION IN INSTALLATION AND OPERATION OF POWER AND MACHINERY UNDER VARYING DEMANDS.

By Julius L. Hornig, Jersey City, N. J.

The question of economy in the construction of steam-engines or motors has been discussed with great ability and science, so that the importance of the subject is generally appreciated and a selection is made from the most approved constructions. The economy by suitable adaptation and installation is a question which requires the same attention.

This article is intended to treat, in general, of the propriety of subdivision in installation where varying service is required. Such cases arise in central stations for supply of power, water, light, etc., or in manufactories, where a number of tools or machines are consuming power at varying demand. The object of the writer is to lead to further discussion and elaboration.

The generators of steam, for power under varying demand, will show higher economy by suitable subdivision. The fact that the highest economy in steam generation takes place when the most perfect combustion takes place, indicates that the temperature of the fire should be kept nearest to this point. Therefore, a variation in the quantity of steam required demands that a variation in grate surface should take place, or, in other words, that more or fewer boilers should be operated accordingly.

The question of combination of smaller and larger boilers is worthy of investigation; and, also, the subject of loss of heat from boilers while the fire is banked, in comparison with the loss of heat from boilers at low temperature of fuel and losses consequent to that.

Steam-engines, built for certain maximum capacity, will naturally show at full service the highest economy. Their loss by friction, inclusive of connections or transmissions to do work at a fixed speed, will be found essentially the same from minimum of work to their full capacity.

When work varies much, as, for instance, in the supply of light, this investigation proves important.

The attached economy-curves are worked out approximately from several systems of indicator-cards, and furnish the following:

COMPARISON TABLE OF USEFUL PERCENTAGE UP TO FULL CAPACITY.

WORK-DIVISIONS.	1.	2.	3.	4.	5.	6.	7.	8.	9.	10.
Per cent for large machine.....	35	55	66	75	80	86	92	95	98	100
Per cent for small machine.....	55	75	86	95	100					
Per cent difference.....	20	20	20	20	20					

The small machine, which has only half the capacity of the large one, doing the same work as the large machine, shows a gain of 20 per cent, if used instead of the large machine when the latter is worked only to half of its capacity.

To consider the loss, a few comparisons only may serve here. In assuming a number of the same class and size of machines installed, and referring to the curve of large machine, the percentage of loss will be found

Working 2 machines, $\frac{1}{2}$ capacity, in place of 1, full = 20
" 3 " $\frac{2}{3}$ " " 2 " = 10
" 4 " $\frac{3}{4}$ " " 3 " = 7
" 5 " $\frac{4}{5}$ " " 4 " = 5

The curve shows a loss of

20 per cent for using a machine only $\frac{1}{2}$ capacity.
34 " " " " " $\frac{3}{10}$ "
54 " " " " " $\frac{3}{20}$ "

The combination of working machines of different capacity must be, evidently, advantageous when using the smaller only for work up to its full capacity, then to change the work on to the larger up to its full capacity, laying the smaller up during the intermediate higher range and adding its service only at demand of rate above capacity of larger machine.

This combining of machines to keep their service nearest to their full capacity must secure the highest economy.

The rate of friction in steam-engine and transmission in other installations will not vary much from electric light machinery taken here as sample, and therefore a similar importance must exist.

This question of economy will apply to the installation of a number of pumps driven by a number of engines where the service varies at times. Also to a series of tools or machines operated under varying demand at factories.

The Holly Water-Works Company carries out a combination of several steam-engines operating one main shaft, and makes steam connection to the cylinders so that some or all may be used for high pressure, or some as second expansion cylinders, as demand may require. This should meet the requirement of subdivision in installation for economical service very effectively.

In first installations, frequently the engines are adopted largely in excess of present service required, as a provision for future extensions, whereby losses are caused in the mean time by increased friction, by the necessity of carrying low steam pressure, and by irregularity in motion due to injudicious expansion.

In transportation service, the timely addition of the so-called hill-horse for vehicles and the pusher for railroad trains, at the steeper parts of

Digitized by Google

the roads, is an established mode of working motors to nearest steady full capacity.

The auxiliary boilers and engines are found in large works for similar assistance.

From boiler tests on best constructed boilers, it is to be assumed that the highest economy is reached by consuming 9½ pounds of anthracite egg coal per hour per square foot of grate, producing 8½ horse-power. This would give the ratio for best subdivision of boilers to suit a subdivision of engines in installation.

THE COPPER PRODUCTION OF THE WORLD.

Messrs. Henry R. Merton & Co., of London, have compiled the following estimate of the production of copper in the world, the figures estimated being marked with an asterisk. The figures, so far as we have been able to check them, give evidence of having been carefully compiled. The difficulties in reaching close figures are very great, because furnace materials and ores are so extensively shipped from one country to the other.

THE COMSTOCK LODE.

The San Francisco *Bulletin* gives the following interesting history of the rise and fall of the Comstock lode mining speculation, which will be found interesting:

The nominal money value of the Comstock lode has undergone many changes in the last twenty years. From 1861 and on for several years, the mines grew in public favor, and values rose rapidly, and with but few radical contractions. From 1868, prices began to fall off under loss of ore-deposits and a diminished bullion yield. This reduction followed the mines until about the close of 1870. At that time, the twenty-five or more leading mines on the lode were rated at a trifle over $4,000,000 in round numbers. Then came the Belcher and Crown Point bonanza, and values again expanded all along the line. This continued for a couple of years, with now and then an interruption. Before the waning influence of an exhausted ore-body in these two mines had come to be seriously felt, the edge of the bonanza in the Consolidated Virginia and California mines was uncovered. This was followed by an unparalleled inflation in values until 1875, when the properties that were thought to be dear five years previously at $4,000,000, were considered (by some at least) undervalued at $275,000,000.

That was the highest valuation ever put upon the Comstock lode. The same mines from that time forward began to decline in value, long before there was any sign of exhaustion of the ore-body that had led to the inflation. Of course, the level of values was much lower when this information got out. The passing of the first dividend by the Consolidated Virginia settled the business with some, and unloading was the order all along. A few held on, under the belief that it was only a dodge of the enemy. The factor of distrust kept the market from going to pieces for some time after the majority had given up all hope of a renewal of dividends. There is occasionally an old stockholder who still believes that both these mines could pay dividends now, if the leading owners would consent to uncover alleged reserves. The several assessments since levied have not changed the opinions of these persons. Their faith is certainly a pleasant diversion, if not too costly. From $4,000,000 to $275,000,000 was a big jump, and from $275,000,000 to about $3,000,000 was an equally big fall. But these are feats which have been accomplished by the Comstock lode inside of twelve years.

We do not remember the lowest valuation for the Comstock lode in the past three or four years. But the valuation of a year ago was quite small. According to a table compiled by us on July 1st, 1882, the twenty-nine leading mines on the Comstock were valued at $3,061,910. These mines are divided into 4,021,560 shares, so that they were selling a year ago for less than an average of 75 cents per share. The leading stock at that time was Union Consolidated, which was selling at $8.62½ per share. Sierra Nevada was then selling at $4.75, Mexican at $4.50, Best & Belcher at $3.25, and Ophir at $2.15. Thus these five mines were selling for a nominal value of $2,336,420, or 76 per cent of the total for the whole twenty-nine. The only two mines selling at $1 per share were the Gould & Curry at $1.25, and the Utah at $1.05. There were eight mines in the list whose stock was rated at only 5 cents per share, and the rating would likely have been still lower but for the indisposition of the Stock Board to split a five-cent piece. There was a great change in these values last month, prices of some of which culminated about the 1st of June. At that time, Hale & Norcross was the leading stock, selling at $8.50, against $8.62½ for Union Consolidated a year ago. Following is a statement of the valuations of twenty-nine Comstock mines on the 1st of June in 1882 and 1883, with the assessments delinquent between the two dates:

	June 1, 1882.	Year's assessments.	June 1, 1883.
Utah	$21,000	$110,000	$61,000
Sierra Nevada	475,000	400,000	675,000
Union Consolidated	862,500	200,000	775,000
Mexican	453,600	352,800	564,000
Ophir	216,720	201,600	389,060
California	54,000	378,000	216,000
Consolidated Virginia	162,000	162,000	432,000
Best & Belcher	327,600	100,800	529,400
Gould & Curry	135,000	162,000	421,200
Savage	33,600	252,000	341,600
Hale & Norcross	33,600	168,000	952,000
Challar	22,400	168,000	453,600
Potosi	44,800	84,000	201,600
Julia Consolidated	5,500	11,000	22,000
Bullion	5,000	100,000	125,000
Exchequer	10,000	.....	45,000
Alpha Consolidated	7,500	.....	75,000
Consolidated Imperial	25,000	25,000	25,000

Totals	$3,061,910	$3,160,540	$7,587,260

As will be seen, the nominal value of these securities has more than doubled within the past twelve months. But much of this increased value is supposed to represent new money that has been put in during the interval in the form of assessments. The nominal value on the 1st of June, 1882, with the assessments delinquent during the year, compares as follows with the nominal value at the close of that year:

Value June 1st, 1883		$7,587,260
Value June 1st, 1882	$3,061,910	
Assessments delinquent	3,160,540	$6,222,450
Increase for the year		$1,364,810

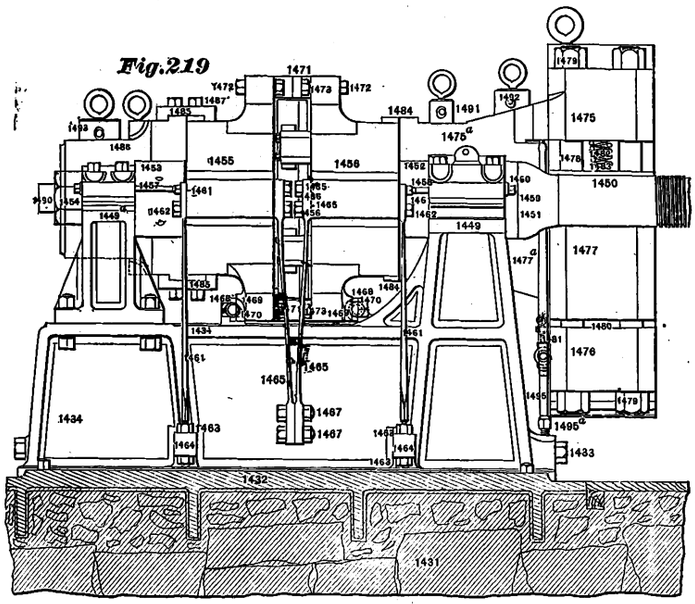
THE BASIC PROCESS AT THE PEINE WORKS.

In November, 1882, the Peine Basic Steel-Works were started, and all difficulties met with in the beginning have now, it is said, been overcome. There are very large deposits of phosphoric ores near Peine, Germany, and the pig made from them has from the start been regarded as particularly adapted to the basic process. The dolomite found in the vicinity of Peine contains 1·35 per cent of silica, 0·26 per cent of protoxide of iron, 2·03 per cent of alumina, 30·12 per cent of lime, 19·21 per cent of magnesia, 0·3 per cent of sulphuric acid, and 44·97 per cent of carbonic acid. It is sharply calcined in a cupola, crushed, and mixed with heated tar, the material thus prepared being used to ram the converters, make brick, etc. The walls of the converters stand from 80 to 95 blows, and the bottoms between 16 and 24 blows. The Ilsede pig contains from a trace to 0·1 per cent of silicon, from 2·5 to 3 per cent of manganese from 2·5 to 3·1 per cent of phosphorus, from 2·7 to 3 per cent of carbon, and a maximum of 0·1 per cent of sulphur; and after melting in a cupola, has the following composition: From 0·7 to 1·2 per cent of manganese, from 2·6 to 3·2 per cent of phosphorus, from 2 to 2·5 per cent of carbon, and a maximum of 0·1 per cent of silicon and 0·1 per cent of sulphur. The pig is decarburized in from 8 to 9 minutes, and the after-blow lasts four minutes, the final addition being 12 per cent of pre-heated ferro-manganese carrying from 54 to 60 per cent of manganese. The composition of the steel varies according to whether it is to be used for wire, structural work, etc., as follows:

	1.	2.	3.	4.
Silicon	0·42	0·47	0·60	0·30
Manganese	0·04	0·06	0·05	0·02
Phosphorus	0·03	0·06	0·04	0·03
Sulphur	0·10	0·14	0·30	0·09
Carbon				

An analysis of the cinder made yielded the following:

	Per cent.
Silica	2·45
Peroxide of iron	5·74
Protoxide of iron	15·10
Protoxide of manganese	2·75
Alumina	2·85
Lime	46·82
Magnesia	1·14
Phosphoric acid	22 23
Sulphuric acid	0·38
Sulphur	0·54



THE WATER-EJECTOR IN MINING.—In the Bleiberg District, Austria, a very interesting application of the ejector has been made in mining, a description of which is given in detail by Herr Ed. Makuc in the *Oesterreichische Zeitschrift*. A Korting ejector has been driven there by hydraulic power, to raise the water from a winze. It now lifts 366 gallons a second from a depth of 92 feet, and uses 435 gallons of power water with a head of 617 feet, thus showing an efficiency of 12 per cent. It is expected, however, that this power will suffice to carry the winze down to 200 feet, so that the efficiency then would be fully 20 per cent. The hydraulic ejector is now working only six hours a day, doing the work of 16 men at hand pumps in twenty-four hours. This system is therefore well worthy of the attention of all those who must sink at isolated points below a tunnel level in which a head of water is available. It would probably prove very useful on the Comstock lode.

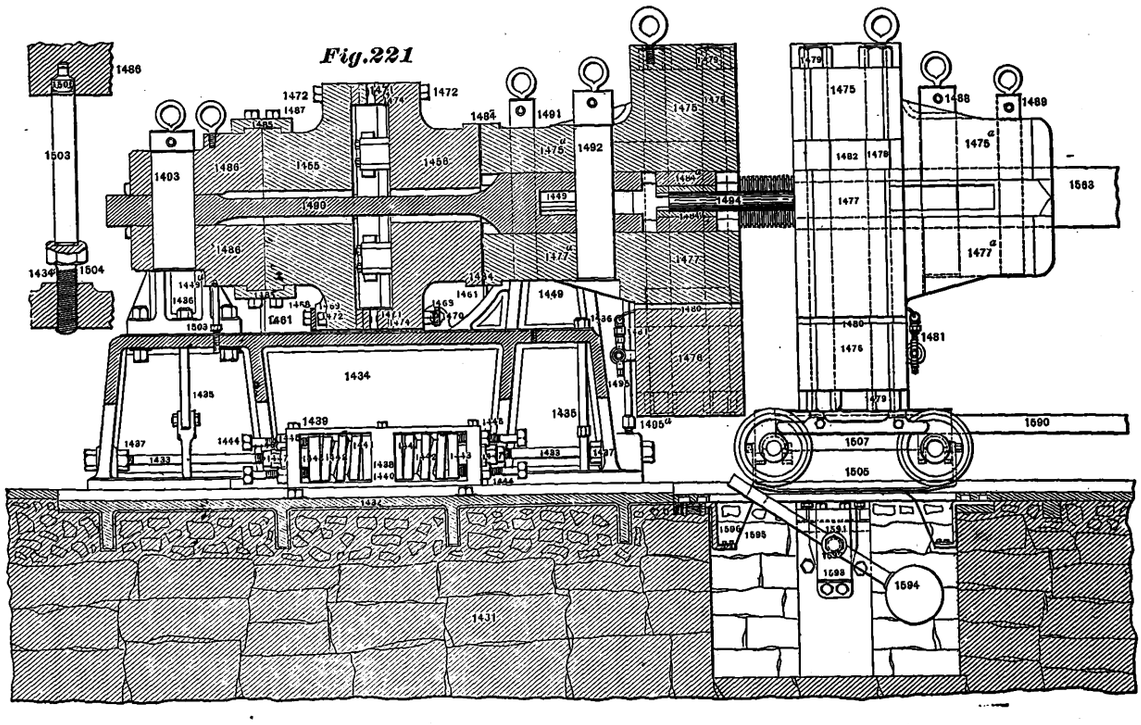
THE EMERY TESTING-MACHINE AT WATERTOWN.

Until quite recently, special circumstances have made it impossible to give more than a general description of the great Emery testing-machine at Watertown Arsenal, Mass. The machine, illustrations of which we give this week, was built for the United States Board to Test Iron and Steel by Mr. Albert H. Emery, and before it was accepted by the Board, the following tests were made: A link of hard wrought-iron 5 inches in diameter between the eyes, was slowly strained in tension and broke at

722,800 pounds, and next a horsehair seven one-thousandths of an inch was tested and was found to break at one pound after stretching 30 per cent. These tests may serve to give an idea of the power and the delicacy of the machine, which has no rival the world over.



Before proceeding to a detailed description of the machine, a general outline of its construction will be useful. It consists of a hydraulic press, which is adjustable within a certain range as to distance, from the weighing apparatus fixed at one end of the machine, the two being connected by a pair of screws eight inches in diameter and forty-eight feet long, and so arranged that specimens from one inch to thirty feet in length and up to thirty inches in width can be tested. Our general view of the machine gives a good idea of its proportions and arrangement.

Figures 219, 220, and 221, reproduced from the plates attached to the patent, for which we are indebted to the kindness of the editors of the *American Machinist*, give the construction of the most important parts in detail. Fig. 219 shows a side elevation of the scale and of the machine, and Fig. 220 a plan of it.

Fig. 221 shows a longitudinal section of this end of the machine, with the scale-holder, that is, the holder which seizes the specimen and secures it to the scale, and shows in elevation the straining holder, that is, the holder which seizes the specimen and which is drawn backward or pushed forward by the straining press.

From a description prepared by Mr. Emery for the *American Machinist*, and from the patent specification, we take the following points relating to the construction:

1431, Fig. 221, represents a foundation of any suitable construction. To the bed-plate 1432 is secured a movable bed 1434, by means of bolts 1435, secured permanently to the bed or foundation, and provided with the clamp-nuts 1436, by which the bed 1434 is forced to its bed-plate with any necessary friction. The holding-bolts 1435 extend down through clearance-openings in the masonry or concrete bed, and are anchored to metal plates at bottom. The clearance-openings allow free recoil to the beds without bending the

holding-bolts. 1433 represents horizontal stay-rods, which may or may not be connected at their center, and are fixed at their ends by clamp-nuts 1437 to the movable bed 1434. These rods pass longitudinally through a case or bearing 1438, which is permanently attached to the bed-plate 1432 by screw-bolts 1439, and is constructed with a central abutment 1440, for the followers 1441, which receive pressure from the ends of springs 1442. The other ends of these springs bear against followers 1443, which are formed with stems, passing through the ends of the case 1438, and are adjustable therein by means of set-screws 1444, threaded in the ends of the case 1438, and locked in any position to which they may be set by jam-nuts 1445. The rods 1433 pass freely through the followers 1443 and 1441, and are coupled at their

Digitized by Google

inner ends within the center of the case 1438 by a nut 1446, which is adapted to slide within the abutment 1440, and bears against the followers 1441 on either side. The rods 1433 bear on the extremities of the necks of the collars 1443 by nuts 1447, locked by jam-nuts 1448. It will now appear that any movement of the bed 1434, acting through the clamp-nuts 1437, rods 1433, and followers 1441 1443, will compress both of the springs 1442, so that the resilience of both will be exerted to restore the bed to its central or normal position. To the bed 1434 are fixed standards 1449 1449a, constituting pillar-blocks for the straining-screws 1450, which are secured to the pillar-blocks by collars 1451 1452 and nuts 1453 1454.

1455 1456 are a pair of coupled beams constituting alternately and interchangeably the bed and platform of the scale, hydraulic supports being interposed between the beams to receive and transmit the load. These beams are adjustable longitudinally on the straining-screws 1450, so that either which is to constitute the bed of the scale for the time being may be brought firmly home against the nuts 1453 or collars 1452, as the case may be, while the other beam is left free to serve as the platform of the scale. This adjustment of the beams is effected by setting-rods 1457 1458, secured separately to the respective beams 1455 1456, and adjustable in the pillar-blocks 1449a 1449 by nuts 1459, between which nuts and the respective pillar-blocks are interposed metallic washers, and beneath these gum-elastic washers 1460, for the purpose of allowing a slight resilience, to prevent the snapping of the said rods by the concussion incident to the breaking of a specimen. The setting-rods require to have clearance in the pillar-blocks. When one pair is to be tightened to bring the beam to which it is attached against its bearings on the straining-screws, the other pair of setting-rods are first relaxed to free the beam to which they are attached. The weight of the beams is sustained by flexible rods 1461, secured by bolts 1462 to the rear faces of the respective beams, and fixed below by nuts 1463, in lugs 1464, on the movable bed 1434.

1465, Fig. 219, represents spring-plates, which are bolted and secured by the nuts 1466 to the inner faces of the beams, and are strained together at their lower ends and connected by bolts and nuts 1467, so as to exert a strong pressure in forcing the beams together and keeping them firmly on the interposed bearings or pressure-supports of the scale. The plates at the same time serve to hold the faces of the beams parallel by preventing their tipping on the struts 1461, and they serve the further purpose of securing the beams against relative vertical motion. To stay the beams against horizontal motion transversely to the machine, they are held by flexible fixing-plates 1468, Figs. 219, 220, 221, secured at 1469 to the respective beams, and to the pillar-blocks or bed by nuts 1470, by which the beams are adjusted transversely to the machine as required. To firmly secure the beams against relative horizontal motion laterally to the machine, fixing plates or springs 1471, Figs. 220, 221, are employed, fixed at their centers to the respective beams by bolts and nuts 1472, and bolted together at their extremities, as shown at 1473. These springs serve, in conjunction with the springs 1465, to press the beams together on the interposed pressure-supports. The degree of pressure of the springs 1471 is regulated by the interposition of washers 1474, of any thickness required, between the springs and beams, the effect of said washers being to reduce the amount of deflection which is applied to the springs in bringing their extremities together. Similar washers are applied between the springs 1465 and the faces of the beams when required.

The pillar-blocks 1449 1449a may be made separately from the bed and attached thereto, or they may be constructed permanently with the bed. In practice, it is preferred to construct one pair 1449, as permanent parts of the bed, and for convenience of erection and adjustment to construct the other pair 1449a separately and bolt them to the bed, as shown. The coupled beams and the specimen-holder at the scale end of the machine may, either or all, be supported from the movable bed, as shown in the present illustration, or upon masonry or other permanent foundation as preferred. The specimen-holders consist each of three beams 1475 1476 1477. The outer beams 1475 and 1476 are secured together by bolts and nuts 1478 1479. The interposed beam 1477 is movable on the connecting-bolts 1478, constituting one jaw of a clamp, of which the beam 1475 constitutes the other jaw. The movable jaw 1477 is forced up to grip the specimen by the action of one or more hydraulic presses, 1480, Fig. 221, suitable dies 1484a, being interposed between the beams or jaws 1477 1475, with faces formed to suit the specimen to be tested.

1481 represents the pressure-pipe for operating the hydraulic presses 1480. The closing of the jaws 1477 1475 is limited by boxes containing springs by which the jaws are forced apart when released by the hydraulic presses. The two beams 1475 and 1477 of the specimen-holder are formed with projecting cheek-pieces 1475a 1477a, for the attachment of the specimen-holder to the load-beam of the scale or to the straining-bar, as the case may be. For the application of strains of compression (for which purpose the beam 1456 constitutes the load-platform, the load-beam specimen-holder is attached to the beam by bolting to flanges 1434, formed on the specimen-holder and beam, clamps 1485, such as are shown in Figs. 219, 220, and 221, fastened to similar flanges on the beam 1455 and the beam-block 1486 by bolts 1487. In the illustration given, the parts are shown in position for the application of a strain of tension. For this purpose, the cheek-pieces 1475a 1477a of the load-beam specimen-holder are connected to a beam-link 1490 by pins 1491 1492. The link 1490 extends through central apertures, as shown in the coupled beams 1456 1455, and is connected by a pin 1493 with the beam-block 1486, which latter is fixed to the load-beam 1455 by the clamps 1485 and bolts 1487.

1494 represents a specimen undergoing a strain of tension. In this illustration, the beam 1456 constitutes the bed of the scale, being drawn firmly against the bearing-collars 1452, by the setting-rods 1458, while the setting-rods 1457 are released from strain by backing their nuts 1459, so as to leave the beam 1455 free. Clearance is accordingly seen between the beam 1455 and the bearing-nuts 1453, and also between the specimen-holder and the fixed beam 1456. When a strain of compression is to be applied, the relations are reversed, the specimen-holder being in that case released from the beam 1455, and fixed to the beam 1456 by the clamps 1485 and bolts 1487, the said beam 1456 being released from the bearings 1452, so as to serve as the load-platform, and the beam 1455 being drawn firmly against the bearings 1453 by the action of the setting-rods 1457, so as to serve as the bed of the scale. When strains of compression are to be applied to columns or other specimens without the use of the holders, the beam-block 1486 is reversed in position, being clamped to beam 1456 by plates 1486 and bolts 1487, a suitable platform to receive the thrust of the specimen being attached to said beam-block by pin 1493.

The load-beam specimen-holder is supported on rods 1495, Figs. 219, 221, erected on the movable bed 1434, or on the stationary bed or foundation. The lower ends of these rods are screw-threaded, as shown in Figs. 219 and 221, and they are formed with angular collars 1495a, for the reception of a wrench for screwing the rods up or down for the vertical adjustment of the holders. By reason of their length, the rods possess sufficient flexibility to permit the slight movement which the specimen-holder receives in transmitting to the load-beam the strain to be weighed. The load-beam specimen-holder 1475, Fig, 220, is stayed against lateral motion by struts 1496 1497 bearing against the cheek-pieces of the said specimen-holder, and fixed by set-screws 1498 1499, screwed into lugs 1500 1501 on pillar-blocks 1449. The set-screws 1498 1499 are formed with conical or convex ends fitting corresponding cavities in the ends of the struts 1496 1497. The set-screw 1498 is first screwed in, to set the specimen-holder in proper position laterally, and is then locked by a nut 1502. The other set-screw 1499 is then screwed in against the end of the strut 1497, to fix the specimen-holder. The beam-block 1486 is supported on a rod 1503, Fig. 221.

The specimen-holder of the straining mechanism is constructed in similar manner to that already described, and is connected to the straining power by its cheek-pieces 1475a 1477a and pins 1488 1489. This specimen-holder is preferably mounted on a truck 1507, running on the rails or ways 1505. To determine the pressure given to the specimen by the hydraulic holders, so that the amount of pressure known to be necessary to fix and hold the specimen may be applied without injury thereto, the liquid-pressure pipes connected with the accumulator and employed to operate the holder-pressure are connected with pressure-gauges. The load, after being transmitted through the supports to the beam 1456, is carried directly against the projections on the screws 1450, so that the load which is put upon the screws by the straining press at one end of the specimen is exactly balanced by the load put upon the screws by the scale at the other end, this load being transmitted through the specimen, no part of the strain being carried through the foundations. If now the specimen breaks, the screws being under a load of compression, immediately free themselves of this load, putting the entire scale end of the machine in motion longitudinally in one direction and the press end in the opposite direction, these parts moving from each other until the screws are free from their load of compression, when the inertia of these parts under motion will continue their movement until the screws have received a load of tension nearly equal to the load of compression which was upon them, the difference of loading being that due to the loss of friction by sliding the scale end of the machine on its ways and moving the press on its track. The extension of the screws will now cause the ends of the machine to move together until the screws are free from tension, when inertia of the moving parts will expend itself in compressing the screws and in overcoming the friction mentioned. In order that movable bed 1434 may always come to rest in its proper position, buffer springs 1442, contained in boxes 1438 secured to fixed bed, are provided. See Fig. 221. These motions of extension and compression continue until the work of recoil is used up in the friction of moving the ends as mentioned. These vibrations are so rapid that, when the machine was originally tested in breaking a bar of wrought-iron of 20 inches section, they could be neither seen nor felt, but set gauges applied at each end showed the amount of these movements. They are not only unseen and unfelt, but they are also unheard, the noise of the breaking specimen completely hiding any little noise the machine may make, no jar or rattling whatever being detected in any part of the machine.

The pressure is transmitted through the medium of a number of liquid-pressure reducers. The base or receiving-head of the reducer contains small removable pressure-receivers—one for each of the pressure-pipes coming from the load-beam supports. The small pressure-receivers are each constructed with a stem for the reception of the liquid-pressure pipe, and with a small pressure-column attached to the head of the stem through the medium of a pressure-diaphragm and a lining-plate permanently connected at their edges, clamped to the reducer-base by a sealing-ring, and containing the liquid-pressure chamber between them. The delivering-head of the reducer is removable, being connected by the pressure-diaphragm with a separable head forming part of the pressure-column. The main part of this column is stayed at top by a fixing-plate separate from the pressure-diaphragm. Heavy strains are applied by a double-acting hydraulic press with piston-rods extending in both directions—one for applying strains of tension and compression, and also for transverse strains by the use of other accessory appliances, the other for torsional strains, which are applied through the medium of a chain-frame, double chain, and saddle arranged to impart forcible rotation in either direction to a torsion arm or wheel, which is also formed with a worm for applying lighter strains by means of screw-gearing.

THE DOETSCH COPPER EXTRACTION PROCESS.—So little is known in regard to the technical details of the Doetsch process, which the Rio Tinto has been testing on a large scale for years, that the following points in regard to it may be of interest. The raw ore, broken to a uniform size of about 0·4 inch, is piled up in heaps from 10 to 13 feet high, channels being left along the bottom, and vertical draught-holes being provided for. Then about two per cent of salt is scattered over the top of the pile, which is about 45 feet wide. A basin, 30 feet square, is then formed on the top of the pile, and the solution obtained after precipitation of the copper, subsequently saturated with chlorine, is allowed to flow into it. Trickling through this ore, this solution acts upon the copper. It is gathered in gutters, conducted to tanks, and made to flow through long sluices, where the copper is precipitated with metallic iron, the quantity of the latter being less than usual (from 110 to 120 parts per 100 parts of precipitate). The precipitate, which runs from 80 to 85 per cent of copper, is dried on hot iron plates. The solution, after precipitation, is dropped through a coke tower, in which it is met by an ascending current of a mixture of chlorine and hydrochloric acid.

THE LAW AS AFFECTING MINING AND METALLURGICAL INTERESTS.

Relocation.—Secretary H. M. Teller has rendered the following decision in a letter addressed to the Commissioner of the General Land-Office: I have considered the appeal of Mary G. Peck *et al.*, from your decisions of December 19th, 1882, and February 7th, 1883, holding for cancellation mineral entry No. 1882 upon Gold Dirt lode, Central City, Colorado. The original location was made and recorded in 1864, since which time there appear to have been numerous transfers of the property; and it is alleged by applicants that the possessory title by virtue of said location is in them.

The abstract of title in the case fails to verify this allegation. Applicants, however, made a relocation, dated December 22d, 1880, covering the same ground, and using the same name under which the mine was originally located.

Their certificate of relocation sets forth, among other things, that it is make without waiver of any previous rights, and to secure all abandoned, interfering, or overlapping claims.

They, by their counsel, now admit their probable inability to supply all the links necessary to show by abstract that they have title under the original location, and hence they claim under the relocation of December 22d, 1880.

Your decision holds that a relocator must show a complete and unbroken claim of title from the original locator, ending in himself, or prove abandonment of the property by the original locator or his grantee; also, that relocation, using the same name under which the original location was made, coupled with the attempt to furnish abstract of title from the original locator and grantees, shows that applicants claim as purchasers for valuable consideration, and therefore that the relocation confers no new title upon them.

I am unable to concur in these conclusions.

Generally, I see no reason why a locator should be called upon to furnish any facts or data relative to a previous location upon the same ground, or why an inquiry should be instituted relative to antecedent matters, except upon showing of irregularity and of injury to material interests. The law applicable to adverse claims provides how and when such showing may be made in case any rights are liable to be infringed.

In this case, applicants, by their admission of inability to furnish complete abstract of title under the original location, as required by your office, virtually waive all claim based upon said location, and rely solely upon their relocation.

The proceedings pursuant to the relocation appear to have been regular. None of the apparently adverse interests appearing in the abstract of title was asserted pending publication under said relocation, nor has it been since, and no adverse claim can now be filed because of the limitation of law. Sec. 2325 of the Revised Statutes provides that, "If no adverse claim shall have been filed with the register and the receiver of the proper land-office, at the expiration of the sixty days of publication, it shall be assumed that the applicant is entitled to a patent, upon the payment to the proper officer of five dollars per acre, and that no adverse claim exists."

You state that the right of the claimants, asserted by the relocation, has never, to the knowledge of your office, been questioned. All antecedent claims may, therefore, be regarded as having been abandoned, and all rights which may previously have existed as waived. . . . .

Publication is notice to the world of intention, and a challenge to any and all adverse claimants to come forward and assert their rights.

No adverse claim having been filed in this case, all antecedent claims may, as already stated, be regarded as having been abandoned, and the question therefore becomes one solely between the United States and the applicants. . . . . I see no reason why patent should not be granted as applied for under the relocation of December 22d, 1880. If applicants based their title solely on their rights as purchasers, the regulation of your office, to which you refer, might call for consideration; but I find no rule or regulation, and no law, which, on the facts as they appear, would operate to prevent the issuance of patent on the location made by the parties themselves.

Your decision is accordingly reversed. . . . .

Very respectfully, H. M. TELLER, Secretary.

THE PRODUCTION AND UTILIZATION OF GASEOUS FUEL IN THE IRON MANUFACTURE.*

By W. S. Sutherland.

While fitting on a feed-valve to a locomotive, about 1866, it struck me that, if the seams of boilers could be welded instead of riveted, there would be an advantage gained in strength and economy which was worth the working out; and, though still very far from seeing this generally done, yet we have now, through this idea, made some thousands of tons of welded flues, tubes, and parts of boilers by the process which I thought out, and which certainly greatly increases the strength of the joints, and makes the soundness of the welding an absolute certainty. It would be out of place to describe the process referred to further than is necessary to the development of this paper; and therefore I only add that the first question that arose was, how to obtain the requisite heat and apply it economically, and of uniform quality and concentration, upon the parts to be welded. A little consideration pointed out some disadvantages in the smith's hearth, which naturally first occurred to me—namely, that it is practically impossible to insure perfect uniformity of heat by it; that hence welding can only be done by a very skillful smith; that dirt and scoria are liable to get into the welds from the fuel; and that an access of air may get to the metal and burn it, thus destroying the whole of the work. Gas then seemed the legitimate fuel to use; but the gas must not be too expensive, and, to insure uniformity of action, should be supplied with the requisite oxygen or air in proper and definite proportion. But to obtain cheap and suitable gas was not easy, and the only gases that appeared available were coal-gas and Siemens gas. With coal-gas, we were successful, and we welded also with Siemens gas; but experience showed that we wanted a good cheap gas having some special qualities, the first of which was high heating power per unit of volume. I have been unable so far to arrive properly at any other solution of this difficulty than the use of gas made by the action of superheated steam upon carbon, and I found, on arriving at this point, that a method of making such gas had been brought out in America by Mr. Strong. I opened up negotiations with the proprietors of Strong's system, and these resulted in the erection at Birmingham of the first water-gas producer in England, which, so far as I know, works under the method described in the following paragraph: "Part of the fuel is burnt as completely as possible to carbonic acid and water; but the resulting heat is stored up partly in the remainder of the fuel and partly in regenerators, that in the regenerators being made to heat up to a sufficiently high degree a quantity of steam. This superheated steam is passed through the hot fuel, and forms with it carbonic oxide and hydrogen, which go away to be stored up and used." The producer we erected worked well, but it needed a good deal of repair. I was, however, enabled to procure the erection of a second one at Essen, in Germany (now set to work), which does not contain the faults found in the former one, and which, therefore, bids fair so far to answer our expectations. With this producer, we have made per ton of Staffordshire coal 55,000 cubic feet of gas, or about 25 cubic feet per pound of carbon, averaging by volumes approximately—

57	parts	H and hydrocarbon.
35	"	CO.
8	"	Co_2 and N.
100	"	

I have found that, to work well with water-gas (so far as treating iron is concerned), it is necessary to get up to a very high degree (not less than 1200 degrees C., I should say), which, however, can be done without injury to the apparatus if the parts exposed to it be protected by exterior cooling. The quantity of gas above given represents only about from 55 to 60 per cent of the available heat in the fuel; but I believe that by improvements, which may be very simply made, this percentage may be very largely increased, although, since there is a double operation and combustion in making the gas, the loss of heat must evidently be greater than in making producer gas. But this loss is, except when regenerators are used, largely counterbalanced by the higher temperature which can, owing to the absence of nitrogen in the gas, be obtained by its simple combustion, and by its greater heating power per unit of bulk, which enables much smaller mains to be used to convey it, and by the fact that much smaller furnaces may in many cases be employed. A great objection has been made to the poisonous quality of this gas; but I believe that it is no more poisonous than coal-gas, and, from my own experience with producer gas, coal-gas, and water-gas, I am convinced that the hydrocarbons and tarry matters do far more hurt than the carbonic oxide. In fact, it seems to me that the poisonous effects of carbon gases and vapors are somehow proportional to the weight of carbon in the injurious compound; and in that case, the hydrocarbons in coal-gas are quite as deadly, if not more so, as is well shown by the number of accidents that have happened with coal-gas. Compared practically with coal-gas, the heating power of water-gas seems one half; but experience has shown that it may be produced at a cost not exceeding threepence per 1000 feet, after paying for coal, labor, and plant, and that the first cost of plant is not very great; while for simplicity in using it when made, it is far superior to producer gas, and more easily managed.

It will, perhaps, be called to mind by many that numerous attempts have been made to manufacture water-gas in retorts; but an examination and comparison of these proposals with the methods above described show that the intrinsic difference between them lies in the facility which this method allows of raising the steam and fuel to a temperature which would rapidly destroy the retorts, but which is necessary for the attainment of good working results. While working with Siemens gas in 1871 and 1872, I had much trouble with the tar and water which came over with the gas and stopped up the tuyeres, and which it was therefore necessary to condense and separate. Now, it will be evident from what has gone before that, in making Siemens gas, the higher the temperature at the bottom of the producer, the better the gas made, and the less carbonic acid there will be in it. Many people are in the habit of saying that, if coal be made into this gas, there is a loss of sensible heat amounting to about 30 per cent; and they give as a reason the fact that carbon burnt to carbonic oxide really does generate about that quantity of its available heat, which, if the gases be cooled down, would be certainly lost. But they forget the coal-tar and water, which must be distilled off from the fuel, and to do which requires at least 10 per cent of this heat, leaving only 20 per cent to account for. Now, this 20 per cent is very difficult to utilize, and the only satisfactory way that can be practically carried out is to take the heat down to the bottom of the producer again, and make it superheat steam, so as to form some water-gas. This I did at that time by cooling down the hot gas by the air going to the producer, so that at the same time the tar and water were condensed.

But there is a simpler way of doing it. It is well known that increasing the draught of a fire increases its temperature. Then if the draught in the producer be increased, while increasing the heat at the bottom we shall diminish the carbonic acid in the gas, and at the same time enable more steam to be passed into the producer without increasing the carbonic acid. Now, it must be evident that, by the law of conservation of energy, if this heat at the lower p art be ncreased through the quickened draught, it must be at the expense of the heat in the outgoing gas, or else we should have a means of increasing the quantity of heat produced by merely putting a fan on. Therefore, by this simple means alone, the heat of the outgoing gas may be utilized; and practically we find that, while the carbonic acid may be kept down to from 0·2 to 2·5 per cent, the temperature of the outgoing gas often does not reach 300 degrees C., which represents a loss of only about 7·5 per cent of the total available heat of the fuel. There are two ways of accounting for this result. In the first place, it was pointed out by Mr. Lowthian Bell that the descending column of fuel carried down with it about 5 per cent of the heat produced; and, in the second place, the hotter the fuel, the more the air going to supply combustion will be heated by conduction from the glow

* A paper read before the British Iron and Steel Institute.

Digitized by Google

ing fuel just before coming into actual contact with it. Thus the reactions go on and heat accumulates, but always at the expense of the upper portion of the fuel and of the outgoing gases. But to work at this higher speed, the producer must be perfectly accessible, so that it may be easily cleaned; there must be as little tendency to scaffold as possible; and, above all, it should not be greater in size than would allow of a man easily breaking up the fuel in it if it caked over or broke through; or, if it be large, mechanical stirring should be resorted to. The problem is to keep the fuel like a sponge, but without large holes and cavities. With the temperature thus kept down, and the loss by cooling made a minimum, little water is needed to bring it down to the requisite point for condensing effectively the tar and water. And as the higher the velocity or draught, the less is the plant required to treat any given weight of coal, so the outlay per ton of fuel gasified and purified is reduced.

I knew that tar and ammonia-water were worth something, but it was not until some years after these experiments that I got the opportunity of carrying out practically their utilization. In 1878, a plant was erected at the Shropshire Iron Company's works near Wellington, which, so far as taking the tar and water out of the gas is concerned, worked very well, and I am glad to say it is now about to be remodeled and extended. This plant was followed by another at the gold and silver rolling-works of Mr. Kemp, of Birmingham, who required very pure fuel for his purpose, and who told me that a drop of tar occasionally getting on to the material would be fatal. However, this has been working well and constantly for over two years, and I believe that no organized system of extracting residuals from fuel, except in the making of light gas, has ever been carried out successfully before. Other plants on this system are now erecting, and more still are about to be constructed in different places. One has recently been set to work in the alkali-works of Messrs. William Hunt & Sons, at Wednesbury, who have so far expressed their satisfaction with it. The working is made as simple as possible. The gas taken away from the producer has its pitch first thrown down to prevent the passages choking up, and is then passed through a condenser, which, while cooling the gas effectively, can increase the temperature of the water for cooling so as to adapt it to steam-raising. It is then scrubbed, to extract the ammonia and cyanides, etc., and, if drawn from the producer, passes through an exhauster. At the high speed kept up, much of the tar is carried on in waves along the interior surfaces of the mains, and if this were stopped in the ordinary way, the fuel absorbed in horse-power would be enormous; but, observing these waves, I thought that if the surfaces of part of the mains were developed and made porous, and contained in an outer chamber, in which a lower pressure could be kept up than that in the mains, these waves would ooze through the porous surface, and get out of the way of the current, while the difference of pressure would prevent them getting in the way again. Experience has proved this idea to be correct. We make these surfaces of wire gauze tubes, up through which the gas passes, a sufficient number being purposely set up in an outer chamber, from which some of the gas is passed by to the other side of the blower. This apparatus is of course on the pressure side. The dried and cleaned gas then proceeds to do its work. We find no difficulty in getting 1¼ cwt. of good tar per ton of Staffordshire coal, and the ammonia-water we have got up to 4 degrees Tweddel; but in the new plants the scrubber is better arranged, so that we may reasonably expect more and stronger liquor.

(TO BE CONTINUED.)

FURNACE, MILL, AND FACTORY.

Messrs. Johnson & Wilson, No. 91 Liberty street, this city, have, as agents for Saylor's American Portland Cement, issued a catalogue which contains considerable matter of interest to cement users generally, without special reference to the Saylor cement. Messrs. Johnson & Wilson, we may note, are also the agents of the Iron, Steel, and Mining Society of the Austrian Alps, a federation of a number of Alpine works that make among other specialties high-grade tool steel.

W. Hasenzahl, Cincinnati, has lately shipped one of his diamond drills, with complete outfit for prospecting, to Montana. A letter received from the president of the Quincy Coal Company states that the company has been using a drill bought from Mr. Hasenzahl a few months since, and is perfectly satisfied with the machine and its work.

At Kankakee, Ill., a barb-wire manufacturing company has been organized which proposes to manufacture the wire without a license.

Rifenburg & Co. have made a proposition to the people of San Diego, Cal., to begin, on certain conditions, the erection of buildings suited for iron and steel-works. Ground has been selected between San Diego and National City. About one hundred men will be employed, it is stated.

The Boston *Commercial Bulletin* says: "The Edwards Manufacturing Company, at Augusta, Me., has decided to close up all work of improvement on the company property at once, and also abandon the project of a new factory. The reason assigned is, that the valuation placed upon the property by the assessors is excessive, imposing a burden which similar property in the State does not bear, and placing the Edwards Company at a disadvantage in a close and depressed market for cotton goods.

The business of the Jarvis Furnace Company and the New England agencies of the Korting Injector, Armington & Sims Company, engines, Sheffield grate-bars, and Schutte & Goehring's jet instruments will in the future be conducted by a stock company organized under the State laws of Massachusetts, with a capital of $100,000. This company will do business under the name and style of the Jarvis Engineering Company. It will not only take charge of the old agencies, but will do a general engineering and contracting business in putting in steam plants for all kinds of manufacturing purposes. K. M. Jarvis is president; A. F. Upton, treasurer and general manager.

At the late National Exhibition of Railroad Appliances, Messrs. Shields & Brown, Nos. 78 and 80 Lake street, Chicago, made a very handsome display of steam pipe and boiler coverings, which attracted much attention. They also covered over a thousand feet of pipe in the Exhibition building, thus illustrating the merit and value of their coverings to all interested visitors. This enterprising firm was awarded by the Exhibition the silver medal which was offered for the best boiler and pipe covering. There were five other exhibitors present in the same line. Among their patrons are the Pullman Palace Car Company, the Chicago, Burlington & Quincy Railroad, the Edison Electric Light Company, and many others.

The Merrimack Manufacturing Company, of Lowell, Mass., has recently put in a five-inch Curtis pressure regulator for its steam-pump, which throws a ten-inch stream and supplies fresh water to a battery of boilers of 7500 horse-power.

The Ontario Rolling-Mill Company, Hamilton, is making large quantities of angle fish-plates for the Grand Trunk, Canadian Pacific, and Canada Southern railroads.

The new McKenney Tubular Rail Company, of Chicago, will locate its works at La Grange, Mo.

The Duncansville rolling-mill, near Hollidaysburg, Pa., which suspended work for repairs, is now running on full-time.

The rolling-mill of McKee, Anderson & Co., at Beaver Falls, Pa., has shut down for a month.

Five more blast-furnaces are to be added to the five already in operation in and around Birmingham, Alabama. It is now proposed to open several new coal-beds and build new furnaces as soon as the railroads furnish the transportation facilities.

The main shop of the Cleveland City Forge and Iron Company is 80 feet wide by 800 feet long, and has 15 hammers made by the Cuyahoga Steam Furnace Company. Ten of the hammers have a single furnace and cylinder boiler, and five of them have double furnaces and flue boilers. The works can make shafts up to 40 tons in weight, all finished and ready to go into the boat. The axle works have a capacity of 500 axles per day. The coupling-pin plant consists of five machines and five furnaces, with an annual capacity of 10,500 tons. For making links, the works have eight hammers and ten furnaces and six machines and six furnaces, and can make 12,000 tons of links per annum. The machine-shop is stocking up with a large amount of heavy tools: A 60-foot lathe, swinging 60 inches, made in Scotland, and weighing 56 gross tons; a 30-inch stroke slotter, weighing 32 tons, made in Philadelphia; a boring-mill, swinging 16 feet 1½ inches between housings, made at Hamilton, O., and weighing upward of 40 net tons; and a planing-machine, which planes 6½ feet square and 25 feet, with bed 40 feet long and a table traverse of 52 feet, made in Philadelphia, and weighing 36 tons.

The Otis Steel-Works, at Cleveland, have the tracks of the Lake Shore & Michigan Southern Railroad passing on the north, and those of the Cleveland & Pittsburg on the south side. The works have an open-hearth plant, consisting of two seven-ton and four fifteen-ton furnaces, the former having an average capacity, nearly, of 100 tons, and the latter of 200 tons each per week of eleven turns. The maximum has been 125 and 270 gross tons respectively. Pig and scrap or pig and wrought-iron are the raw materials used, no preheating being done. Bottom casting is exclusively practiced at the works, the arrangement being a modification of that originally introduced in Bessemer practice. The product is ingots for variety of purposes, and direct castings, principally heavy work, such as rolls. The plant, if pushed to its utmost capacity, is believed to be able to make forty thousand tons per annum. The most interesting feature of the plant is the Wellman plate-mill, trains of the same design being at work or building at Schoenberger & Co.'s, Pittsburg, the Spang Iron and Steel Company, Pittsburg, and the Springfield Iron Company, Springfield, Ill. The mill is driven by a Porter-Allen high-speed engine, having a cylinder 40 inches in diameter, with 48-inch stroke, and running at a speed of 100 revolutions, with a steam pressure of 80 pounds. The ingots are reheated in three furnaces. The train is three-high, the upper and lower rolls being driven, while the middle roll is an idler. The upper roll is raised and lowered by counterweighted levers. The length of the rolls is 112 inches, the diameter of the upper and lower rolls being 31 inches, while that of the middle roll is 20 inches. They run at a speed of 67 revolutions per minute, and roll down ingots to the well-known Otis plate in one heat. The mill has besides one three-high sheet train driven off the end of the blooming train, and a merchant mill driven by a horizontal engine with 28-inch cylinder and 48-inch stroke. The axle forge contains four Cuyahoga hammers. A recent addition to the works has been a mechanical puddler driven by a two-cylinder horizontal engine.

The Cleveland Rolling-Mill Company recently turned out 100,280 pounds of No. 5 steel wire in one shift, J. P. Edwards having charge of the rolls.

The St. Louis Ore and Steel Company is introducing the Gustin patent hot-bed and straightening apparatus in its rail-mill. This improvement is expected to increase the product 25 per cent, and will save considerable labor.

A well sinking for natural gas by the Central Glass-Works Company, of Wheeling, at a depth of 840 feet, after piercing a thick vein of sand-rock, struck a strong flow of gas. It was conducted from the mouth of the well in pipes and lighted, making a blaze thirty feet high. The gas will be used for fuel in the glass-house. This is the fourth well which has been successfully drilled through to a gas-vein.

Joseph Corns, after a prosperous three years as lessee of the Massillon Rolling-Mill has concluded arrangements by which he and his son became owners of the mill, under the firm name of Corns & Son. It is the intention to enlarge the works considerably, increasing also the working force, which now consists of 150 men. The mill has been running uninterruptedly during all the recent period of depression and uncertainty in the iron trade.

The converting department of the Cambria Iron Company's steel plant is connecting with furnaces Nos. 5 and 6 by means of two railroad tracks, which, when completed, will be used for conveying molten metal directly from the furnace to the converters.

William Todd & Co., founders and machinists, Youngstown, O., have just cast for the Delaware iron mine, in Michigan, three drums, which are 14 feet in diameter and 7½ feet high, and are each cast in one piece, but so arranged that they will easily split in three pieces, for convenience in shipping. Each drum weighs twelve tons, and will hold a cable nearly a mile long. These are undoubtedly the largest drums ever cast in Ohio.

H. K. Porter & Co. have under way at their light locomotive-works a locomotive for pushing rail blooms at the Scranton Steel-Works. It weighs but about three tons, and is only two-foot gauge. The cylinders are five inches diameter and 10 inches stroke. There is no cab, as it will run inside of the steel mill.

The Springfield Iron Company, of Springfield, Ill., expects to have its new steel boiler-plate train running at an early date. It will roll plates up to nine feet wide.

Messrs. Howard & Morse, of this city, have issued a catalogue descriptive of the Blackman power ventilator, an exhaust-wheel which has been coming into favor rapidly for a variety of purposes, prominent among which are the ventilation of dwellings, hospitals, theaters, vessels, mines, the exhausting of steam, moisture, dust, noxious gases, etc.

Among the recent contracts secured by the Porter Iron Roofing Company, Cincinnati, Ohio, are the following: Iron roofing and siding to cover all the buildings of the Western Nail Company, Belleville, Ill. Iron roofing and siding for the Isabella Furnace, Barneston, Pa. This was made of galvanized iron, the best and most expensive. Galvanized iron, No. 20 gauge, for the County Buildings at Winnemucca, Nevada. Iron roofing and siding for oil-works at Newport, Arkansas. Roofing and siding for Chicago Tire and Spring-Works, Chicago, Ill. Iron roofing for large mill at Socorro, New Mexico. Iron roofing for the match-works at Brownsville, Me. Iron roofing for large smelting-works at Tombstone, Arizona.

MINERAL PATENTS GRANTED BY THE UNITED STATES LAND-OFFICE.

The following mineral patents will be promulgated by the General Land-Office the present week as of date July 1st:

CALIFORNIA.

MARYSVILLE DISTRICT.

Abbott Quicksilver Mining Company, Abbott quicksilver mine.

COLORADO.

CENTRAL CITY DISTRICT.

Paul Lindstrom, placer. Edgar Freeman, Rising Sun lode. Joshua S. Reynolds, Specie Payment lode. John G. Roberts, Camel lode. Charles M. Hill *et al.*,

Digitized by Google

Buena Vista lode and mill-site. Charles F. Wells, Arabian lode. Charles W. Pollard, Olympic and Titan lodes. Thomas McCallister, IXL lode. Samuel Heilner, Great Sphinx and Cleopatra lodes. Mary G. Arnett, I. O. U. lode. Park Disbrow, Etta Disbrow lode. Cornelia C. Munson *et al.*, Badger lode. Jabez Rippin, Lucas lode. Nels Johns, Enterprise lode. Michael Kelly, Big Spring lode. H. J. Robbins *et al.*, Old Timer lode.

DEL NORTE DISTRICT.

Alexander H. B. Harenc, Radcliff lode.

LAKE CITY DISTRICT.

W. Weston *et al.*, Iron Clad lode. Herman Beckarts *et al.*, San Juan lode.

LEADVILLE DISTRICT.

Scott Hayes, Wisconsin lode. John W. Reed *et al.*, Lillie lode. W. S Ward, Bismarck lode. J. O. Hallmark *et al.*, Bonanza King lode. John McGranahan *et al.*, City of Durham and Little Rose lodes. Charles O. Edman *et al.*, Mobile lode. Theodore A. Fellows *et al.*, Old King Cole lode. W. J. Wilson *et al.*, Carleton lode. Charles J. Moore *et al.*, F. C. Garbutt lode. New York & Colorado Mining Syndicate and Company, Patch lode. Mathias Stauffacher *et al.*, Little Annie lode. James Camoran *et al.*, Camoran lode. J. C. Taylor *et al.*, G G lode. James C. Spenas, Yale lode. Chippewa Consolidated Mining Company, Comstock lode.

PUEBLO DISTRICT.

Christian Wahl *et al.*, Dakota Maid and Boss lodes. C. L. Wall *et al.*, Queen of the Valley lode. Lumber City & Silver Cliff Mining Company, Copper King lode. Richard Irwin *et al.*, Cymbeline lode. Valley City Mining Company, California lode.

NEVADA.

CARSON CITY DISTRICT.

Ferdinand S. Van Zandt, Brooklyn, Cooper, and Galatia lodes. Manuel San Pedro *et al.*, San Francisco lode.

EUREKA DISTRICT.

C. L. Bray *et al.*, Kemp & Keene Consolidated lode.

NEW MEXICO.

Benjamin F. Gumm *et al.*, Miguel Otero lode.

MONTANA.

HELENA DISTRICT.

Joseph Rosenthal *et al.*, Mapleton lode. Michael C. Cotter *et al.*, Empire lode and mill-site. John J. McRae *et al.*, Glengarry lode.

UTAH.

SALT LAKE CITY DISTRICT.

Benjamin Bachman *et al.*, Governor lode. Thomas J. Gibbons *et al.*, Benton lode. M. J. Snedaker *et al.*, Allegan lode. Lars S. Anderson, coal.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY.

TOMBSTONE MILL AND MINING COMPANY.—The following dispatch, just received, shows the June output from the mill and furnace to be $91,400 gross. The fourth level of the West Side is opening in a good body of high-grade ore. The new strike in the Tough Nut has increased in size and value at a depth of seventy feet. The local papers say that the company is now purchasing all the smelting ores it can get, and is paying the highest market price for them.

GRAHAM COUNTY.

GLORIETTA.—This company owns seven claims located about a mile and a half southwest of the Detroit Company's mines. It has already spent $2500 in development-work. Work has been resumed on the Micawber. A shaft 100 feet in depth has been sunk on this claim, and two levels started, one at 50 feet, which is in 25 feet; and another at 75 feet, which is in 15 feet. The company proposes to run the latter level 50 feet further, through the deposit of iron, and then to sink another shaft.

PIMA COUNTY.

The Caledonia copper group, twenty miles south of Picacho station, on the Southern Pacific Railroad, has been sold to J. D. Power. The ore gives an average of 26¼ per cent copper.

CALIFORNIA.

MONO COUNTY—BODIE DISTRICT.

BODIE CONSOLIDATED.—The average assay value of the pulp is $36.42 per ton; that of the tailings, $5.90 per ton. There were 209 car-loads of ore hoisted from the mine, 145 car-loads of which were from the 740 to 770 foot levels.

STANDARD CONSOLIDATED.—There were extracted and shipped to the mills 1461 tons of ore during the past week.

SYNDICATE.—The mill is running on ore from the mine.

PLUMAS COUNTY—GREENVILLE DISTRICT.

CRESCENT.—At the mine, all work except pumping is suspended.

GOLD STRIPE.—The mill has been started up, but will be kept running day shift only for some time. Some prospecting is kept up, and upon the result of this, future operations will depend.

GREEN MOUNTAIN.—No new developments yet to report in the big tunnel. The drift goes ahead rapidly and steadily. The ledge does not yet prospect enough to warrant milling any of the ore. In the mean time, ore enough is taken from the upper tunnels to keep both mills fully supplied.

COLORADO.

BOULDER COUNTY.

KEYSTONE.—The mine is now worked after many years of idleness. A portion is worked on a lease.

MOUNTAIN LION.—This mine has been recently purchased by Eastern capitalists, who purpose to develop it extensively. A forty-stamp mill is to be erected shortly.

SENATOR HILL.—The mine has been making regular shipments for some time. The developments consist of three shafts, all of which are in pay. The property is worked on contract.

CHAFFEE COUNTY.

The following statement shows the large amount of development-work done in the various properties in Monarch District:

	Feet.		Feet.
Black Tiger, tunnel	420	Buck's, tunnel	400
Black Tiger, shaft	75	Middle Fork, tunnel	290
Monarch, shaft and drift	837	Mount Ætna, tunnel	400
Eclipse, tunnel	620	Greeley, tunnel	1210
Eclipse, shaft	130	Columbus, tunnel and drifts	3000
Silent Friend, tunnel	117	Tabor, tunnel	650
Crœsus, tunnel	200	Beta, tunnel	612
Gene Moore, tunnel	300	Beta, shaft	140
Lost Wonder, tunnel	369	Zephyr, shaft and drift	642
Lexington, tunnel	195	Buda, shaft and drift	400
Michigan & Big Chief, tunnel	140	Denver, tunnel	889
Continental Divide, tunnel	452	Kangaroo, tunnel	1500

The grading of the railroad from Maysville to Garfield and Chaffee is nearly completed and ready for ties. A force of from 200 to 300 men is kept constantly at work, and it is expected that the cars will be running by August 15th, when the output of the Monarch District will be greatly increased.

CLEAR CREEK.

Following is a statement of ore-shipments from Georgetown and vicinity during the month of June:

Shipped from	Tons.	Value in dollars
Boston & Colorado Works	415	$52,700
Silver Plume Sampling-Works	202	20,200
Miners' Smelting Company	150	16,000
Mendota Lode	82½	6,485
G. W. Hall & Co	40	8,000
A. P. Stevens (estimated)	150	30,000
Total	1,039½	$133,385

BRITISH QUEEN.—The tunnel which has been started at the base of the mountains is now in 125 feet, and will intersect the old Baker mine at a distance of twenty-five feet more. Contracts will then be made to run it 200 feet farther. The Baker mine has over one mile of levels, shafts, and winzes, that produced large sums of money ten or twelve years ago and have been mostly abandoned since. The company has commenced, within the last year, to clean out these old openings, with very satisfactory results.

GOLDEN LEAF.—The mill for the reduction of the quartz taken out of this lode, on Soda Creek, will be in running order shortly. The shaft on the lode is about 90 feet deep, and the character of the free-milling ore is still unchanged. A new adit has been started on the vein close to the mill, which shows stamp-dirt three feet wide. When the mill is in running condition, it is the intention to treat custom ore for all those developing mines in close proximity to the above property, and for no others.

NEW YORK & COLORADO.—A contract has been made with Messrs. Fraser & Chalmers, of Chicago, for the erection of a fifty-ton stamp-mill.

REPUBLICAN MOUNTAIN.—This company, an English incorporation, has been steadily driving its Everett tunnel ahead, on Republican Mountain. It is in from 700 to 800 feet, having already cut the Morning Star lode, being within 100 feet of the Edward Everett, and having at least three patented lodes to cut within the next 400 feet, all belonging to this company. On the Morning Star, a drift has been run some 100 feet westerly of the tunnel, and a shaft raised to surface. The tunnel cuts it at a depth of 250 feet. The ore milled runs from 300 to 500 ounces silver. As soon as all the company lodes in the line of the tunnel have been cut, systematic development of each of them is proposed. Among other properties included within the company's patented properties are the Alhambra, Ogden, and Parr claims, with several hundred feet of shafts and other developments.

SNOWDRIFT.—Major Fulton has received a favorable five years' lease and bond on this mine, and will work it hereafter on his own account.

DOLORES COUNTY.

RICO REDUCTION COMPANY.—The works which were recently started, says a dispatch from Rico, prove a perfect success with the local ores. These works have been enlarged and improved since last year.

GILPIN COUNTY.

KING.—The main shaft has now attained a depth of 315 feet. The ore assays 1½ ounces of gold, 18 ounces silver, and 54 per cent lead per ton. Sinking will be resumed as soon as a contract for 100 feet can be let.

RARA AVIS.—Work has been stopped at the Whitney mine, owing to defective hoisting machinery. It is rumored that the company will remove the engine and boilers from the mill building to the mine. There is a sufficient capacity to hoist from a depth of 1000 feet.

VALLEY VIEW MINING AND MILLING COMPANY.—The annual meeting was held in Central City recently. On the return of the President, work will be resumed upon the property, the larger portion of which has been developed.

GRAND COUNTY.

READY CASH.—A strike of some importance has been made in this mine. A fine streak of mineral of a high grade, varying in thickness from fourteen to eighteen inches, was encountered in the cross-cut tunnel driven to tap the Ready Cash. The tunnel is in over 200 feet.

LAKE COUNTY.

The Leadville *Herald* gives the following statement of the bullion production for the quarter ended June 30th. The Royal Gorge is estimated:

SOURCE.	Tons of lead.	Ounces of silver.	Ounces of gold.	Value.
Arkansas Valley (bullion)	2,051¾	357,786	877	$595,757.60
Arkansas Valley (ore)	1,953½	196,348	..	391,779.80
La Plata Smelter	1,772	331,315	840	540,726.50
Cummings & Finn	1,937	335,316	195	536,077.60
Harrison Works	1,572½	119,208	1,036	293,328.80
American Smelter	1,500	135,000	1,582	315,140 00
Elgin Smelter	96	11,402	118½	23,551.20
Eddy, James & Co (ore)	6,996	831,865	.....	1,544,692.66
Royal Gorge, Canon City (ore)	400	35,455	.. ..	75,000.00
Leadville G. & S. Mill	.....	55,768	.....	61,344.80
Shields Mill	.....	7,471	12½	8,250.00
Tabor Mill	.....	20,296	16	22,645.60
Miscellaneous	.. ...	2,000	200	6,520.75
Total second quarter	18,278¾	2,429,120	4,877	$4,414,815.31
Total first quarter	.....	.....	.....	3,662,662.00
Total for six months of 1883	.....	.....	.....	$8,077,477.31

In the above calculations, lead is figured at $90 per ton; silver, at $1.10 per ounce; and gold, at $20 per ounce.

The *Herald* reports the ore output of the mines situated on the different hills at Leadville for the month of June as follows:

	Tons.		Tons.
Carbonate Hill	5,701	Printer Boy Hill	1,030
Yankee Hill	1,376	Fryer Hill	4,604
Breeze Hill	1,243	Little Ella Hill	1,340
Iron Hill	17,402	Sugar Loaf Mountain	310
Rock Hill	1,851		
Total			34,857

CATALPA.—The mine produced, during the month of June, 945 tons of ore. The output is the result mainly of tribute-workers. Exploration-work carried on in the eastern portion of the property has not met with the success anticipated. The rises made from the incline driven eastward from the bottom of the upper shaft have reached the limestone and porphyry contact. At the points where the contact was cut by the rises, it was found destitute of contact matter and ore, the two formations making a close contact. The next movement will be the exploration of the northeast corner of the Catalpa claim, near the line of the Evening Star mine. Negotiations are in progress with the Colorado Iron and Steel-Works. If that company will pay four dollars a ton for the iron ore of the Catalpa, the manager will contract to supply the company with from fifty to one hundred tons of ore per day. The ore contains from fifty to sixty per cent of metallic iron, a small quantity of manganese, and only a trace of silica. Assays show the ore to have a value of from two to seven dollars in silver to the ton,

Digitized by Google

which is not enough to make it profitable ore to mine and reduce for the silver it contains.

CHRYSOLITE.—The company has begun the shipment of iron ore to Billings's smelter in Utah. The iron is to be used as a flux in lead smelting, and trial lots only have been sent so far.

HENRIETT.—At present, the mine shows greatly increased resources, and a very large production of ore may be looked for in the future.

SUMMIT COUNTY.

ROBINSON.—It is stated that the directors have acceded to the request of Mr. Greer for a modification of his lease, and that a new lease was signed on the 28th ult., which alters the royalty payable by Mr. Greer in several important respects, relieves the lessee from the duty of erecting concentration-works at the mine, and divests the lease of some of its most objectionable features. It now remains to be seen how it will work in practice. Mr. Greer returned on the 4th. The shipments vary from four to five cars a day, and the grade remains the same. In June, the total shipments were 87 cars, as against 92 in each of the two previous months, the falling off being due to the temporary stoppage of work, due to the water.

DAKOTA.

Much work will be done this summer in the tin mines recently discovered in the Harney range.

ALTA-LODI.—A complete reorganization of this company has been made, and work will be resumed upon the mines some time in August.

CALEDONIA.—The superintendent reports, June 24th: Ore produced, 1050 tons. The pump is in place in the winze, and a good incline track is down. Will start drifts to-morrow. The mill is running to its full capacity.

FATHER DE SMET.—The superintendent's report, for week ended June 30th, shows: Ore extracted from first, second, and third levels, 2750 tons. Ore milled, 2700 tons. Golden Gate north header in 158 feet: tramway level rise up 80 feet.

GARFIELD.—This company has a force of men employed upon the Charter Oak and other mines on Silver Creek.

STAND-BY.—Under the arrangement made between the company and the Boston capitalists, the latter will construct railroads to other mines in the vicinity, and keep the mill running to its full capacity. This contract is to hold good at least two years. Other mining property, water-rights, etc., in the immediate vicinity will probably be purchased by the company, and it is stated that negotiations for several transfers are already opened. Work will shortly be commenced on the Stand-by property, with the intention of thoroughly testing its value, and a large quantity of ore will be milled during the present year.

GEORGIA.

CONSOLIDATED GOLD MINING COMPANY OF GEORGIA.—The treasurer's report, presented at the third annual meeting, shows receipts and disbursements as follows:

RECEIPTS.

Proceeds of bullion, Ivey mine	$38,289.64
Proceeds of bullion, Bast mine	22,482.11
Dividends on 13,130 shares treasury stock	5,877.20
Proceeds sale treasury stock to pay for right of way for new ditch	1,000.00
Balance on hand June 1st, 1882	199.38
	$67,848.33

DISBURSEMENTS.

Expenses at Ivey mine	$10,022.24
" " Bast mine	9,932.87
Construction account of Ivey mine, including right of way for new ditch	1,775.97
Office expenses	1,847.69
Dividends	44,000.00
Balance on hand June 1st, 1883	267.56
	$67,848.33

The superintendent states that, during the year, seventeen miles of canal to convey the waters of Cane Creek to the Ivey mine have been built, with sufficient reservoirs for the storage of water. This is an exceedingly valuable work, as it gives a supply of water for hydraulic work, and also furnishes power for running the mill. The new sixty-stamp mill has been completed, and the work done at the Bast and Ivey mines has been going on steadily with favorable results.

MAINE.

Reports are, that the Blue Hill mining camp is a busy place at present. The Douglass, Stewart, and Blue Hill mines are actively at work, and, collectively, employing a large force of men. The Douglass is steadily producing and shipping refined copper, and good progress is made in the construction of the calcining-furnace.

EDGECOMB.—This mica mine is vigorously developed. It is situated in the town of Edgecomb, about three miles from Wiscasset. The product of this mine is said to be equal to the best North Carolina mica. In mass it is wine-colored, but, when split, is white. There seems to be an inexhaustible supply; and the deeper the shafts are sunk, the better the quality.

MICHIGAN.

The production of the mines named is given for the month of June as follows:

	Tons.
Calumet & Hecla	1754
Quincy	275
Franklin	177
Atlantic	159
Allouez	112
Pewabic	68
Peninsula	58
Wolverine	46

CHAMPION IRON COMPANY.—A portion of the company's lands, located in the vicinity of Michigamme, has been leased to parties who will explore it for gold, the latter being said to exist in quantity sufficient to warrant a thorough search.

ETNA.—The company has paid the stipulated bonus of $10,000 for the privilege of mining ore at a royalty of 75 cents per ton.

ILLINOIS.—Work will be resumed in the near future, probably under an arrangement with one of the most prominent companies operating on the range.

MCCOMBER.—Operations have been resumed.

MONTANA.

JEFFERSON COUNTY.

GREGORY CONSOLIDATED.—The extraction of ore at the present time is confined principally to the third and fourth levels. The daily output is about 35 tons, which will be largely increased on the completion of a projected concentrator that will have a daily capacity of 100 tons. The smelting capacity of the company will be amply sufficient to treat the product of both the old and the new concentrator on the completion of the latter. In the mean time, it is the intention of the company to take all necessary measures for the energetic and deep development of the mine. A new hoist with a capacity to sink 1000 feet has been already ordered, and will be started into operation as soon as possible. The facilities of the company for the easy and comparatively inexpensive reduction of Gregory ore are exceptionally good. Wood and water are in abundance, with nearness of plenty of fluxing ores and the certainty of early opportunities for cheap railroad transportation.

SILVER BOW COUNTY.

ALICE.—The mines of this company are looking well. The ore-house is full, and the eighty-stamp mill is running regularly.

BELL.—Drifting has been commenced from the old workings in the 240, to connect with the new shaft at the 270. The 400-foot station is nearly completed, when a north drift will be started from that level, to tap the vein underneath the old workings, to which an uprise will be run. The smelter is making a successful run. The concentrator is repairing, and will be started up on ore from the low-grade dump.

MOULTON.—Reports show the usual amount of development-work. The ore uncovered is of a good grade. A streak in the ledge about twelve inches wide assays as high as 400 ounces. The mil is running steadily.

NEVADA.

GEDDES & BERTRAND.—The mill is running regularly, reducing about 60 tons of ore that goes from $24 to $29 per ton. The cost of treating is said to be $8 for mining and $6 for milling.

GRAND PRIZE.—The Grand Prize-Argenta hoisting-works at Tuscarora were burned to the ground June 30th. The loss by the fire is $30,000, the outlay necessary to replace the building and machinery. There was only $10,000 insurance.

NEW HAMPSHIRE.

MASCOT.—Another rich strike of ore is reported on this property at Gorham. The vein in the tunnel at the base of the mountain, which has shown well hitherto, has been steadily improving in appearance as work progressed, and among the many streaks of galena with which the vein-matter is interspersed is one more than four inches in width. The mine is showing most encouraging prospects. The work of development is carried steadily forward, and meanwhile, preparations for the erection of the concentration-works are progressing favorably.

NEW MEXICO.

According to the Albuquerque *Journal*, the injunction obtained lately by Brunswick & La Rue against H. B. Ferguson, who represents the interests of the Jack Winters heirs in the North Homestake mine at White Oaks, has been dissolved by Judge Bristol, after a full hearing.

Work has been commenced on the large smelter of Mr. Billings, at Socorro. It is going to be at present a two-stack of 100 tons capacity daily. It has machinery capable of running 400 tons by supplying the additional furnaces. There are about sixty men at work now, and it will be completed by August 15th, for treatment of the Kelly ore. The railroad track is partly completed to the smelter, and cars will be run to it very shortly.

OHIO.

The vein of mica in Jackson township is still undeveloped, the parties discovering having thus far failed to secure a lease of it. They claim to know exactly where it is, but decline to give any information either to the owner of the farm or to any one else before securing the lease.

UTAH.

The Salt Lake *Tribune* gives the following statement of bullion receipts in that city for the first half of 1883. The ore receipts have been excluded, because the ore reduced in the furnaces there appears for its full value in the bullion shipments of the smelters. The table, however, by no means includes all the bullion production of Utah. The Mingo smelter makes no daily or weekly reports, and its work is not included. Other smelters, also, are not reported. None of Silver Reef except the Stormont is given. The immense ore-shipments of the Crescent, going for the most part directly to their destination outside the territory, are also not reported. It is estimated that, if all were included, the bullion product for the half-year would amount to four millions and a half. January, $473,025.83; February, $577,041.24; March, $664,571.66; April, $563,341.77; May, $506,565.10; June, $453,480.20. Total, $3,238,025.80.

The Copper Belt mill, at Marysvale, has been consolidated with the Pluto mine, for the purpose of working its ores, and the mill is to be put in operation as soon as possible. Messers. Holderman and Nicholson have gone there for the purpose of pushing work on the mill, and they hope soon to be producing metal. This consolidation extends only to the mill and mine, and not to the Pluto Mining Company.

SILVER REEF.

Wells, Fargo & Co.'s shipments of silver from Silver Reef, for the month of June, amounted to $36,924.14.

VERMONT.

VERMONT COPPER MINING COMPANY.—The New York *Tribune* states that the probable result of the recent strike and riot at Vershire will be that the company will fall into the hands of a receiver. The actual condition of the affairs of the company and the prospects of the mine are briefly stated as follows: There is a bonded indebtedness of half a million dollars, with interest past due. The floating indebtedness is nearly $200,000. The corporation which owned the mine for many years previous to a year or two ago was known as the Vermont Copper Mining Company, Smith Ely, President. The miners, up to within a few months, worked at contract prices, and, after the decline in copper, the output of ore was done at a loss. The company became involved in financial difficulties and litigation last year. The Vermont Copper Company was formed to succeed the old corporation, with E. Ely Goddard, President. F. M. F. Cazin was manager under the company, and the firm of Goddard & Cazin run the corporation store. It is claimed that Cazin expended a large sum of money in worthless improvements, a crushing-mill being built at an expense of $30,000, which has not been used. At last, the property was deeded back to the Vermont Copper Mining Company. Bonds were issued and the creditors of the company were paid largely in these securities. Meanwhile Goddard sued Cazin for libel. The firm of Goddard & Cazin dissolved partnership. Cazin was arrested. Application is made by Cazin for the appointment of a receiver of the property. Attachments have been laid on the property, including one in the name of the Eagle National Bank of Boston for $20,000. One week ago, the men refused to go to work. The president of the company, Smith Ely, declined to pay the miners their just dues. He also refused to put any more money into the business.

VIRGINIA.

VIRGINIA STATE MINING COMPANY.—An excellent quality of roofing slate is quarried from the company's 4040 acres tract at Snowdon, near Rope Ferry station of the Richmond & Alleghany Railroad, Amherst County, twenty-four miles west of Lynchburg, where it has a bed of slate three miles long and three quarters of a mile wide. These slates are on the eastern slope of the Blue Ridge, and very convenient to the railroad.

WYOMING.

The copper mines at Hartville are producing a large amount of copper. The smelter is running continually, the mines are developing, and there is already more ore on the dumps than the smelter can treat for some time to come. The mines are producing largely, and, taking into consideration the fact that they were discovered only three years ago, the outlook is very favorable.

The last find reported near Cheyenne promises to be of great value. An Iowa company has been at work for several weeks on a quartzite ledge, near Buford station, on the Union Pacific Railroad, and at the bottom of the new shaft has struck native copper scattered in fine grains and leaves, all through the vein. The ledge is over 120 feet across, and cuts the formation at nearly a right angle.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, July 13.

Our mining market has shown a slight increase in activity compared with the small dealings of the past weeks. The sales, which were pretty uniformly distributed—more so than usual, in fact—aggregated 224,910 shares, against 138,740 last week.

From the Comstock there has been no news, authentic or otherwise, to affect values, which have on the whole, however, exhibited a little more strength. California has reacted slightly, sales ranging between 11@15c., while Consolidated Virginia has fallen off from 45c. in the beginning of the week, to 40c. at the close. Sierra Nevada fluctuated between $3.40@$4.50, closing at $4.35, while Union advanced from $4.75@$5.50, and closed to-day at $5.25. Sutro Tunnel held its own.

The Leadville stocks exhibited signs of weakness, Iron Silver quietly holding at $2.95@$3.10, the latter being higher than usual. We refer editorially to the successful issue of some of the litigations in which this mine is involved. Amie, Little Pittsburg, and Climax have been weak, while Chrysolite, under active trading, advanced to $1.30, but declined later on, closing at $1.20. There was little interest in the other Leadville stocks.

Bodie stocks have excited no more interest than usual. Standard has held its own. Bulwer reached $1 on Saturday, but records no sales since then.

Among the Tuscarora stocks, Navajo has again rallied, advancing from $2.25@$3, closing at the latter figure. The rest have been quiet.

In the miscellaneous list, we note particularly, as the first transaction for a long period, the sale of 1000 shares of St. Joseph Lead at $7. Alta-Montana has reached bed-rock at 1c. per share. The mine was sold under foreclosure proceedings this week for $719,000. The bulk of the indebtedness of the company is to local bankers. Eureka has dropped off under light sales to $4.50. Aside from the poor outlook for the mine, the future of lead is not promising. Horn-Silver, after advancing to $7.75, declined and closed at $7. Northern Belle has been a little more active than usual, and has held its own. Silver King has dropped off to $9. Sonora has been the most active stock on the list, recording over 100,000 shares, advancing from 18 to 40c., but closing at 25c.

At a recent meeting of the Henriett Mining Company in London, organized to work the Henriett mine of Leadville, it appears that the English engineer, Mr. Henty, who reported on the mine, very much overestimated the reserves. Mr. Moffatt, the vender, has signified his willingness to pay 20s. each for all shares offered previous to the 27th of July, the shareholders retaining the two dividends of 2 per cent each which they had received.

Another Leadville mine has been launched on the London market. This time it is the Silver Cord, with a capital of £100,000 in £1 shares, £10,000 cash being asked.

The stock operations of the palmy days of mining speculations have left behind them a fruitful crop of litigation, among which we may note the suits of Sylvester H. Langdon, a stockholder of the Mack Morris Mining Company, against Clinton B. Fisk, José F. Navarro, A. V. Stout, and others; and of E. Nutt against the trustees of the Nueve Minas de Santa Maria, one of the Roberts schemes. Mr. Nutt alleges that the mining land owned by the company, in the State of Sonora, Mexico, was purchased for $17,000 from its original owner, and that the purchaser for this sum then sold it to the company for all but seven of the 100,000 shares into which its capital stock of $25,000,000 is divided. He charges that the property was certainly not worth more than $500,000, and that the purchase of it by the company for stock representing a par value of $24,999,825 was a fraud, particularly in view of the fact that most of the shares were given by the seller of the land back to the trustees of the company or their nominees, and by them put on the market for their own benefit as full-paid stock. He purchased 300 of the shares at $2 each, and he now seeks to compel the trustees to account to the company, for the benefit of himself and other stockholders, for the $24,000,000 of stock which he alleges they have fraudulently obtained and disposed of to their own advantage.

MEETINGS.

Dunderberg Mining Company, Nos. 90 and 92 Broadway, Room 37, New York City. The adjourned meeting of the stockholders for the election of trustees, and such other business as may be presented, will be held August 1st, at three o'clock P.M.

DIVIDENDS.

The Castle Creek Mining Company, of Idaho, has declared its regular monthly dividend (No. 14) of three per cent, payable July 16th.

The Copper Queen Mining Company, of Arizona, has declared a quarterly dividend of $125,000, payable on July 16th, 1883. Transfer-books close July 13th, and reopen July 17th.

The Mount Pleasant Mining Company, of California, has declared a dividend (No. 2) of fifteen cents per share, payable at the office of Messrs. Laidlaw & Co., No. 14 Wall street, New York City, July 16th.

The Homestake Mining Company, of Dakota, has declared its usual monthly dividend of $50,000, payable on the 25th inst., at the office of Messrs. Lounsbery & Haggin, No. 15 Broad street, New York City.

The Quincy Mining Company, of Michigan, has declared a dividend (No. 30) of $3.50 per share, payable August 15th, to stockholders of record July 24th.

PIPE LINE CERTIFICATES.

The week has been one of considerable activity and of considerable excitement, the market giving way. The official figures of the United Pipe Lines (in barrels) for three months are as follows:

U. P. L.	April, 1883.	May, 1883.	June, 1883.
Net stocks	33,123,726	33,366,470	33,656,342
Certificates issued	25,39[illegible],241	27,084,933	28,591,101
Credit balances	7,730,485	6,281,537	5,065,241
Receipts	1,856,793	1,895,283	1,842,012
Deliveries	1,584,047	1,637,203	1,536,751
Excess receipts	272,746	258,080	305,261

A comparison of the June report with that of a year ago is given below in barrels:

U. P. L.	June, 1882.	June, 1883.	Changes.
Net stocks	26,966,476	33,656,342	Inc. 6,689,866
Certificates issued.	21,282,496	28,591,101	Inc. 7,308,605
Credit balances	5,683,980	5,065,241	Dec. 618,739
Receipts	2,419,935	1,842,012	Dec. 577,923
Deliveries	1,796,712	1,536,751	Dec. 259,961
Excess receipts	623,223	305,261	Der. 317,962

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

		Opening.	Highest.	Lowest.	Closing.	Sales.
July	7	$1.14⅝	$1.14⅞	$1.13½	$1.14⅝	1,975,000
	9	1.14⅝	1.14⅞	1.13¼	1.14⅛	2,080,000
	10	1.14⅛	1.14½	1.12½	1.12½	2,011,000
	11	1.12⅝	1.12⅝	1.11⅜	1.11⅞	2,112,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, July 12.

There has been a little more animation in the market for copper stocks this week, and prices show considerable firmness, especially for the two leading mines. Ingot copper is steady at 15¼ cents, and as the production for June of the companies above alluded to shows quite an increase over the same time last year, it is fair to suppose that, even at the present price of ingot, the mines will continue to be remunerative to the stockholders, which fact tends to bring buyers into the market for all the stock offered. Calumet & Hecla advanced from $242@$243, with sales of less than 50 shares all told for the week. The usual quarterly dividend of $5 per share has been declared, payable August 15th, to holders of stock July 14th. Quincy advanced from $49@$51½, with more than usual changing hands. The announcement of a dividend of $3½ per share had rather a depressing effect on the stock to-day, and it was freely offered at $50 regular to $49, seller 60. It was generally expected that the dividend would not be less than $5, the same as last year. Franklin sold at $10, the same as last week. Osceola declined from $20@$19½. Atlantic sold at $11. Huron, at $1⅝@$1½; and a small lot of Allouez at $1¾.

In silver stocks, at the old Board, there has been absolutely nothing doing. Sales of Bonanza at $2¼ @$2⅜, Sullivan at $1¼, and a small lot of Silver Islet at $4, tell the whole story. At the Mining Exchange, there has been more activity; but the trading has been confined to a few specialties, and prices do not show large fluctuations. Bowman continues to be the leading stock, with sales of about 17,000 shares at 27@33c. Massachusetts & New Mexico was rather dull in the early dealings at about 7@8c., but was more active to-day, with sales at 9c. The bonds are quoted at 16@18 per cent. Empire, rather quiet, but firm at 20@25c.

At the afternoon Boards, Huron sold at $1½. Sullivan declined to $1. San Pedro sold at 35c. Bowman, 20@28c. Massachusetts & New Mexico, at 9c. Catalpa, dull, 53c. bid, 56c. asked. Quincy, 49@ 50c. Silver Islet, $4 bid.

BULLION MARKET.

NEW YORK, Friday Evening, July 13.

The firmness noted in our previous postings was only temporary, in consequence of weaker Eastern exchanges, and, with lower sterling exchange here, our figures are reduced as per accompanying table. The market is weak and likely to go somewhat lower.

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.

Week ended July 7th	$36,865
Corresponding week last year	58,127
Since January 1st, 1883	6,976,822
Corresponding period last year	2,005,380

Foreign Bank Statements.—The governors of the Bank of England, at their weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 4 per cent. During the week, the bank lost £19,500 bullion; but the proportion of its reserve to its liabilities was raised from 35 3-16 to 42 5-16 per cent, against 39⅛ per cent at the same date last year. The bank, July 12th, gained £16,000 bullion on balance. The weekly statement of the Bank of France shows losses of 7,825,000 francs gold and 6,900,000 francs silver.

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14⅛ per cent, to arrive at actual value.

MINES.	States.	Month of June.	Year from Jan. 1st, 1883.

METALS.

NEW YORK, Friday Evening, July 13.

Official returns place the German exports and imports of metals as follows, the metric ton being the unit:

	Imports.	Exports.
Sheet-lead	46	1,076
Pig-lead	1,972	41,916
Litharge	2,184	2,393
Rolled copper	159	1,409
Ingot copper	10,579	6,097
Copper wire	71	588
Brass	436	1,265
Nickel	173	55
Quicksilver	396	6
Pyrites	108,709	27,517
Sheet-zinc	148	14,270
Spelter	4,395	56,478
Zinc ores	24,567	8,846
Tin	5,636	667

Copper.—This metal is beginning to show elements of greater strength. The export engagements have been heavy, and we note that both Baltimore and Anchor brands are quoted in London, although the figures are still considerably below Best Selected, with which they rank in quality.

The latest reports from Arizona are by no means encouraging to the producers there. In the Globe District, only one company is running, and in Clifton the Scotch company seems to have got pretty deep into the mire, through the incapacity of the managers, who do not appear to be able to smelt the siliceous ores of the Metcalf group without the ferruginous ores of the Longfellow, from which they have been cut off by the cave in that mine. The Arizona product will, therefore, not be as heavy as has been anticipated, while the only metal that now reaches our market from Butte is that from the Parrott, the product of the other smelters being shipped abroad.

We note this week sales, at private terms, for home consumption, of between 700,000 and 800,000 pounds of Baltimore copper, and of about 200,000 pounds of Lake ingot and wire bars for export at 15½c. England cables Chili Bars to-day at £63 15s.@£64, showing firmness there.

Tin.—The market has been quiet. At the Exchange, there have been sales during the week of 250 tons, the latest to-day being 25 tons spot at 21c. We quote for jobbing lots, spot cash, 21¼@21⅝c. for Straits, 21¾c. for Lamb & Flag, 21½c. for Australian, and 22c. for Banca. London cables to-day, £92 10s.@£92 15s.

Lead.—Our market has been very dull, with only a few small sales, not aggregating more than 200 tons of Common at 4⅜c., and 4·35c., and it does not appear to be salable at the latter figure now.

Messrs. John Wahl & Co., of St. Louis, wire us as follows to-day:

Our market has declined slowly since our last report; there are more sellers than buyers, and hence prices are weak. Ordinary Missouri has been sold here to Eastern consumers at 4·10c., sales being 130 and 170 tons of Refined at 4·10½c.

Messrs. Everett & Post send us the following dispatch:

The market is very flat and weak, and buyers are holding off, taking only for immediate requirements, as they expect a decline. Offerings, however, are very light, especially of Refined. We note sales of 300 tons of Common at 4·15c., and 200 tons of Refined at the same figure.

Spelter.—The market is extremely dull, in spite of the fact that among all metals this ore is apparently most favorably situated. Good ordinary domestic brands are freely offered here at 4·50c. England cables £15@£15 2s. 6d.

Antimony.—Nothing has been done. We quote Cookson's nominally 10⅝@10⅝c., and Hallett's 9⅝@9⅝c. for large lines.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, July 13.

The total stock in bond at the ports of New York, Philadelphia, Boston, Baltimore, and New Orleans are, according to the same authority:

	Jan. 1. Tons.	June 1. Tons.	July 3. Tons.
Pig-iron	6,330	7,635	4,242
Spiegel iron	4,131	2,609	1,396
Old rails	5,504	2,665	2,711
Scrap iron	1,384	3,023	4,008
Scrap steel	456	306	560
New iron rails	6,642	4,119	255
New steel rails	4,816	4,587	.....
Grand total	29,263	24,944	13,172
Decrease during June, 1883			11,772

Official returns place the exports and imports of iron and steel of Germany as follows for the year 1882, the unit being the metric ton:

	Imports.	Exports.
Iron ore	785,359	1,621,182
Merchant iron	15,785	144,407
Wire	3,496	227,415
Pig-iron	283,009	186,938
Scrap	8,048	59,548
Plate and sheet	3,157	44,204

The following figures, showing the imports of iron and steel and the stock in bond at New York, have been compiled by Mr. Edward J. Shriver, Secretary of the New York Metal Exchange:

ARTICLES.	IMPORTS. May.	June.
	Tons.	Tons.
Pig-iron	10,707	12,206
Iron ore	2,157	1,509
Spiegel iron	3,981	5,704
Old rails	179	178
Scrap iron	1,308	1,839
Scrap steel	4,176	7,981
Steel blooms	209	372
New steel rails	10,928	3,572
New iron rails	.....	.....
Steel wire rods	9,952	13,963
Iron wire rods	393	600
Swedish iron	1,262	2,098
Iron bdls. and bars	78	100
Iron beams	236	401
Hoop-iron	115	2
Sheet-iron	279	453
Russia sheet-iron	.....	.....
Steel bdls., bars, etc	678	476
Steel tires and forgings	298	312
Iron tubes	.....	.....

Steel bdls., bars, etc	.....	.....	.....
Steel tires and forgings	.....	.....	.....
Iron tubes	.....	.....	.....

American Pig.—The feeling continues to improve, although furnace agents do not report any heavy sales, and we are able to note this week that the improvement has spread from No. 1 to No. 2, which is now also attracting more attention. At the Metal Exchange, the following transactions have been reported: Monday, 200 tons No. 1, September, at $22.75; Tuesday, 400 tons No. 1, September, at $22.75, and 200 tons, October, at $22⅞; Thursday, 500 tons No. 1, September, $22⅞, and 100 tons No. 1, October, $23; and to-day, 100 tons No. 1, November, $22⅞. We quote for spot, according to brand, $21.50@$23 for No. 1 Foundry, $19@$20 for No. 2, and for Gray Forge, $18.50@$20. Bessemer pig is quiet and unchanged, buyers' and sellers' views lying apart. England cables 50s.@51s. 3d. f. o. b. Spiegel is dull, with 20 per cent quoted at $31. There is little demand.

Scotch Pig.—The market is feeling the impetus of better figures for American Pig, a firmer market in Glasgow, and higher freights, which are cabled 7s. 6d. Sales during the week aggregate from 800 to 1000 tons in lots at the following quotations ex ship: Coltness, $23.75@$24; Langloan, $23.75@$24; Summerlee, $23@$23.50; Dalmellington, $21.25@$21.50; and Eglinton, $21@$21.50.

At the Exchange, the following cable quotations were received: Coltness, 59s. 3d.; Langloan, 60s.; Summerlee, 57s.; Gartsherrie, 57s. 9d.; Glengarnock, at Ardrossan, 54s. 6d.; and Eglinton, at Ardrossan, 48s. 6d. Warrants to-day were 47s.

Rails.—There is very little doing, although the inquiry for small parcels for early delivery is fair, $38@$39 at mill being quoted. There have been transactions for winter delivery, bids not being higher than $36.50, which the mills decline to accept.

Old Rails.—Trade continues very dull, with but few transactions to base quotations upon. We quote Ts $21@$22. We quote a sale of 600 tons of cropends at the Exchange for July delivery at $25 delivered.

Scrap.—There is very little business to report, quotations remaining nominally $21.50@$22.50 ex ship for No. 1.

Philadelphia. July 12.

The past five days have developed very little of special interest, outside of crude iron. The trade is in an attitude of expectation on both sides. Neither manufacturers nor consumers are willing to make a

move while they regard the market as liable to sudden change. Pig-iron is unexpectedly strong, especially in the higher grades. Offers were made to-day for some of the special brands at $23.50, and they can not be had. Regular buyers are favored, and hence outsiders find stocks sold ahead, frequently at 50 cents less than market rates. Standard makes run from $22@$23, and in some cases future delivery can not be had, even at these figures.

Outside of half a dozen brands, there is no difficulty in buying iron at reasonable rates. Nothing in good No. 1 has been heard of under $22. More or less No. 2 is offered and sold as No. 1, owing to the scarcity. No. 2 ranges from $20@$22, and some little is selling at the latter quotations, though well-known makes are going at $20, and sales have been heard of at $19.50.

Gray Forge iron continues dull. Some inquiry has been developed, but transactions are of rare occurrence. Quotations range from $17@$19. A few transactions of a few hundred tons each were close in the neighborhood of $18 at furnace. Some makes are held firmly at $18.50, and the very best makes are sold up. Some inquiry is coming for Bessemer pig, but buyers will not purchase, except at figures which makers can not accept.

In Muck Bars, an improving feeling has shown itself for the best makes, and sales are known of at $35. A few hundred tons of Charcoal Blooms sold at $60@$61, while poorer makes sold as low as $56.

Anthracite are $47@$49, and Scrap Blooms, $44.

Merchant Iron.—The closing down of a good many mills and the uncertainty as to how long they may be out has given the retail trade in Merchant Bar a little more firmness and activity. Brokers are receiving orders at 2·20c., and stores are doing business at 2·25c., and in some cases at 2·30c. in small lots. Buyers are not making any particular move as yet, knowing that the output will prevent any upward tendency and that Western iron can be relied upon in any event. Several inquiries are in hand, but buyers are not ready to close. They are feeling around with a view to future purchases.

There is less activity in nails, and selling prices are unchanged. The action of the Western nail men will help this market. Car-load lots are sold at $3, and there is very little disposition to cut prices. Stocks are not large enough to create very active competition.

Structural Shapes.—Within a day or two, some inquiries have come to hand for structural iron, which manufacturers expect to have orders for in a week or ten days. Quotations are 2·40c. for Angles, 3·20c. for Tees, and 3·50c. for Beams and Channels. It is said that some large contracts will be given out during this and next month for bridge work.

Plate and Tank Iron.—The low prices in plate iron have brought out a good many orders within a few days, and five or six of the larger mills here are now crowded. Negotiations which had been pending for a long time were suddenly closed. Very few mills are short of orders, and at present figures there will be no difficulty in keeping busy.

Sheet-Iron.—More business was received this week at 4@4½c. Galvanized is specially active. A large amount of building will be begun immediately, as is indicated by the number of permits taken out for work to be finished before winter.

Wrought Pipes and Tubes.—Steam Pipes can be bought at 72½ off list, and Tubes at 60 per cent off. Low prices have brought out buyers, and the week's business has been large.

Steel Rails.—Most of the business transacted this week in Steel Rails was in small lots at $39@$40.

Old Material.—Old material is without any activity whatever, and rails are nominally $21.50 for Tees.

Scrap.—Yard-men have managed to dispose of a few hundred tons of Cast No. 2 and No. 1 at prices ranging from $17@$24.

Pittsburg. July 11.

No improvement has been developed during the past ten days. Pig-iron has gone so low that furnacemen are not desirous of taking large contracts at present figures, as cost is barely obtained. Stocks are accumulating in the Mahoning and Shenango valleys. Supplies at Wheeling are large, and, in Alleghany County, stocks of iron are accumulating in consequence of the shutting-down of mills for repairs. Buyers are without stocks, and will not anticipate requirements until after the resumption, which will take place about August 1st.

The demand for unfinished iron is dull, and prices range from 1·80@2c. A few mills in this district are still running. The demand for nails has temporarily fallen off, and prices are $2.90.

The action of the nail manufacturers was a foregone conclusion, and will lead to an improvement in prices for the fall trade.

A good inquiry has developed for sheet-iron and wrought-iron pipe.

Building activity will absorb the bulk of the production of the mills furnishing construction iron.

Steel rails are quoted at $38@$40, and small orders are placed at the latter figure.

Old rails are quoted at $22.50, and negotiations will be closed for summer shipments abroad at that figure.

Spikes are 2·60c. Crop-ends, $25. No. 1 Scrap, $24.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, July 13.

Anthracite.

Current business is quiet, middlemen being fully occupied in placing the coal taken by them, while buyers are as a rule content to await developments. The local retail trade has not as yet shown any disposition to take more than is necessary to meet the small current demand. The opinion seems to prevail that a very quiet month will follow the June maneuver, though it is likely that it will prove of considerable interest in other ways. Full-time work is to begin next week, and the leading companies will strain every nerve to put a heavy quantity of coal Westward. How soon friction will be developed by the efforts of the new-comers, remains to be seen. A few specks are making their appearance on the horizon even now. So long as peace reigns in the West, our markets will to some extent be benefited, as the pressure to sell will be less. Should the struggle there, which is looked upon by many to be inevitable, cease to be local and begin in general, then there may be some irregularities here.

From Philadelphia come reports of scarcity, which, however, are not likely to be more than temporary.

The report circulated in the anthracite region that the Philadelphia & Reading Coal and Iron Company will work the mines of the Lehigh & Wilkes-Barre, as early as August 1st, is not confirmed here. That this will be done in the near future is beyond doubt, but it is not believed that the matter will be consummated before the first of September.

Advices from the East are not rose-colored, and the general business situation has not as yet shown any signs of improvement, which, however, is not looked forward to until the close of the month or the middle of August.

Bituminous.

The only transaction of interest worthy of being recorded this week is the sale of 10,000 tons of Cumberland coal to the Fitchburg Railroad at $2.85 at Georgetown, which would be equivalent to about $4.35 delivered in Boston. Business is quiet and dull, with a slight undercurrent of strength. Consumers recognize that prices for bituminous coal are very low. There are many evidences that, for steam-making purposes, bituminous coal on the seaboard is gaining ground considerably. We quote Clearfield coal $3.75@$4.10, and Cumberland $4.10@$4.40, according to quality. Freights are declining, a fact which is favorable to all the shippers who have heavy contract engagements, but is not of any great influence upon current business.

STATISTICS OF COAL PRODUCTION.

Belvidere-Delaware Railroad Report for the week ended July 7th:

	Week.	Year. 1883.	Year. 1882.
Coal for shipment at Coal Port (Trenton)	717	46,650	34,254
Coal for shipment at South Amboy	4,451	405,430	410,056
Coal for distribution	8,173	393,908	360,499
Coal for company's use	1,501	74,494	65,566
Total	14,842	920,482	871,375
Increase		49,107	
Decrease			

Comparative statement of the production of anthracite coal for the week ended July 7th, and year from January 1st:

Tons of 2240 lbs.	1883. Week.	1883. Year.	1882. Week.	1882. Year
Wyoming Region.

St Line&Sul.RR.Co.	1,173	31,100	712	27,782
Total	274,350	14,401,622	491,434	13,183,738
Increase		1,217,884		
Decrease	217,084			

The above table does not include the amount of coal consumed and sold at the mines, which is about six per cent of the whole production.

Total same time in 1878 ..... 7,510,905 tons.
" " " " 1879 ..... 12,562,206 "
" " " " 1880 ..... 12,932,194 "
" " " " 1881 ..... 12,932,194 "

The increase in shipments of Cumberland Coal over the Cumberland Branch and Cumberland & Pennsylvania railroads amounts to 339,027 tons, as compared with the corresponding period in 1882.

The Transportation of Coke over the Pennsylvania Railroad for the week ended July 7th, and year from January 1st:

Tons of 2000 lbs.	Week.	Year.
Penn. RR. (Alleghany Region)	450	50,353
West Penn. RR	1,525	54,608
Southwest Penn. RR	34,026	1,045,820
Penn. & Westmoreland Region, Pa. RR	3,001	117,196
Pittsburg, Penn. RR	15	469
Snow Shoe (Clearfield Region)	396	10,758
Total	39,413	1,279,204

Horsford's Acid Phosphate
In Seasickness.

S. S PARKER, Wellington, O., says: "While crossing Lake Erie, I gave it to some passengers who were seasick, and it gave immediate relief."

FOR SALE.

ENTIRE PROPERTY OF

The Farwell Con. Mining Co.,

Situated in Independence Gulch, Pitkin County, Colorado, consisting of

Extensive Gold Mines, developed,

Large tract of

Placer Claims, undeveloped,
One 30 and One 20-Stamp Mill,

Nearly new, in Complete Running Order, with Steam and Water Power.

Tunnel and Mill-Sites, with Water-Rights, Ditches, Pipes, etc.,

And all improvements. Greater part of property with patent title. No application to lease need be made. For further information address

W. B. DICKERMAN,
74 Broadway, New York City.
WILLIAM H. PHILIPS,
214 West 19th street, New York City.
ROBERT E. BOCRAEM,
Leadville, Colorado.

DIVIDENDS.

OFFICE OF QUINCY MINING COMPANY.

NEW YORK, July 11, 1883.

DIVIDEND NO. 30.

THREE DOLLARS AND FIFTY CENTS ($3.50) per share will be payable August 15th next, to holders of record 24th inst. Massachusetts holders will be paid at the office of Mr. N. H. Daniels, 2 Change Avenue, Boston. By order of WILLIAM ROGERS TODD, Treasurer.

OFFICE OF THE HOMESTAKE MINING COMPANY, MILLS BUILDING, 15 BROAD STREET, NEW YORK, July 13, 1883.

DIVIDEND NO. 59.

The regular monthly dividend of FORTY CENTS per share has been declared for June, payable at the office of the Transfer-Agents, Lounsbery & Haggin, Mills Building, 15 Broad street, on the 25th inst.

Transfer-books close on the 20th inst.

LOUNSBERY & HAGGIN, Transfer-Agents.

THE Second Annual National Mining and Industrial Exhibition was opened at Denver, on the 17th, with much festivity.

THOMAS COUCH, of Salt Lake, Utah, one of our most experienced and reliable mine foremen, is at present at Butte City, Montana, where he may be addressed for a short time. He offers his services either to examine or to manage mines.

OUR correspondent, "Specular," who closely follows developments in the great Lake Superior District, this week discusses the present condition and the prospects of the ore mines. He states the condition of that great industry frankly, as he finds it; but he does not by any means give encouragement to those furnace-men who believe that all they need to do is to wait in order to obtain their supplies of raw material at their own figures. On the whole, his view is not as gloomy as that of Mr. JAMES M. SWANK, who, in a letter to the *Bulletin*, dated July 6th, says: "From the best information that we could obtain, we came to the deliberate conclusion that this year's production of iron ore in the Lake Superior region will not materially exceed one half of the production of last year: it will certainly not reach two million tons."

THE "boom" for which the members of the Metal Exchange have gradually been getting into shape has come, and pig-iron and tin have been chosen as the favorites. With a plethoric treasury, $65,000 being in bank, and a large number of members who have had ample experience in bulling and bearing cotton, petroleum, grain, and stocks, a lively time may be looked forward to for a while. The Metal Exchange is established on a firm basis, and is bound to become an important element in the trade. It is useless to discuss whether it is a desirable factor or not. Its existence can not be argued away or its members be frowned down. In the metals, it has a field of considerable promise, so far as concerns the magnitude of the business which may come to it. Tin has been the foot-ball of speculators on both sides of the Atlantic for years, and has naturally promptly assumed a prominent *rôle* at the Exchange. Lead has almost annually felt the results of speculative dealings, and spelter has been repeatedly touched in the same way. Years ago, copper was quite a favorite metal with outsiders; but the unwavering policy of the Calumet & Hecla Company, backed by its great power, so thoroughly discouraged the speculative element that for a long period it has been entirely absent. The recent great increase in the product, distributed among a number of producers, would appear to create opportunities, and it does not seem impossible that in the future we may witness speculative manipulation simultaneously on both sides of the Atlantic.

Pig-iron and old material have seen periods of wild speculation by outsiders in this country. We need only point to the boom period, when, notoriously, merchants and capitalists of all classes "plunged" deeply; but we question whether any thing approaching in magnitude the Scotch warrant market can ever be built up in this city. In other branches of the iron trade, there is little room for speculative maneuvers. Such is briefly the field, so far as we can survey it, of those who have begun to deal in futures in the Metal Exchange. That the introduction of this means of creating business is capable of doing some good, and a good deal of harm, those in the trade will be ready to admit. There is a powerful opposition to it; but those who dread its influence will not be wise if they sit quietly by. It will undoubtedly divert some business from other cities to New York, and from other channels; but we question whether in times of ordinary activity the general public will do much toward its support.

THE INDIAN GOLD MINING INDUSTRY.*

During the past few years, Americans have been so busy here in endeavoring to save from the general wreck the more meritorious mining ventures floated during the period of speculative excitement that they have had little time or disposition to watch the course of events abroad. There was little that was consoling in the fact that, while they were struggling in the trough of the seas, enthusiastic British investors were giddily riding on the foaming crest of a huge wave. The history of the Indian gold mining excitement, which Mr. D. E. W. LEIGHTON has written in a clear, critical manner, furnishes a striking illustration of the dangers into which mining is carried. It is instructive because it is, we believe, the first instance in which the distribution of the funds invested by the public is made known. The Indian gold mines have been an extreme case, and have been paralleled in this country only in a few instances; but the manner in which they were floated in the English market is, unfortunately, only too often repeated. Mr. LEIGHTON distributes the blame for the swindles perpetrated and the errors committed pretty uniformly, and does not spare the dear investing public, for which so many display tender sympathy and echo unbounded indignation after it has awakened to its folly, while few are willing to assume the thankless task of warning and advice.

The first one of the mines of the Wynaad and Kolar districts was put on the London market in December, 1879, and in rapid succession others followed until within nineteen months forty-one companies had been formed, of which thirty-three, having a nominal capital of twenty millions of dollars, proceeded to allotment. The interest in this class of ventures made it possible to carry values near par, and in many cases far above it, until in July, 1881, after a month of the wildest boom, the bubble burst. Out of the thirty-three companies, fifteen have until now passed through the hands of the liquidator, the majority of them probably never having done a stroke of mining work. Nearly all of the rest of them may be supposed to have been actually formed with the object of extracting gold from the ores supposed to exist in the Wynaad and Kolar districts. These eighteen companies, according to Mr. LEIGHTON, have a combined capital of £2,682,500, of which £306,000 is still left unspent in the treasuries of the companies; £1,546,500 may be set down as the amount of money paid for the properties, and £130,000 as the capital uncalled for, or calls not paid in, leaving as the money actually spent £700,000. Of this sum, it is estimated, not less than £194,000 was expended for law charges, directors' fees, agencies, and traveling, thus leaving only £506,000 as the amount actually laid out in plant and development-work, the former calling for £338,000 and the latter for £168,000. The vendors and promoters of the Indian gold mines got £1,195,000 in cash and £1,297,000 in shares, a part of which, we presume, they realized on. These are hand-

* THE INDIAN GOLD MINING INDUSTRY, ITS PRESENT CONDITION AND ITS FUTURE PROSPECTS. By D. E. W. LEIGHTON. Madras: Higginbotham & Co. 1883. 8vo, 70 pages; with Appendix, xxii pages.

Digitized by Google

some figures for mere prospects and exhausted coffee estates; but they would be comparatively insignificant, if, in the wide territory covered, there were proved really gold deposits of magnitude and permanence. Unfortunately, the millions spent thus far in machinery and development have not even given assurance on that point. Up to the close of 1882, there have been crushed 3901 tons of quartz yielding 536 ounces of gold. Mr. LEIGHTON urges, and no one acquainted with mining operations will deny the force of his argument, that it is impossible to bring an industry such as the extraction and treatment of gold ores to full working order within as brief a period as the impatience of directors and stockholders generally expects, especially when the mines are located in an inaccessible region, like the Wynaad, which is 30 or 40 miles from the coast, with an ascent of 3000 feet. BROUGH SMYTH, who first drew attention to and fully described the district, undoubtedly underrated these difficulties. But making full allowance for this fact, it must be humiliating to those engaged in the district to confess that after two years' work they know little or nothing more of the deposits than when they began. Mr. LEIGHTON does not acknowledge this in so many words, but it may clearly be read between the lines. He deplores that so much money, comparatively, was expended for machinery, while so little was done in the mines, and winds up his review with the statement that "it may be said with some confidence that the time is now near at hand, when, in the Wynaad, at any rate, the existence or non-existence of gold in paying quantity will be an established fact." We sincerely hope that the next monsoon will furnish the proof, and that then Indian mining companies will take the sound advice which Mr. LEIGHTON offers. The money wasted will then at least have been spent to some purpose, in acquiring, though at a fearful price, experience.

DAVID DUNCAN.

In the death of Mr. DUNCAN the coal trade has lost one of its most distinctive representatives, one who spent his entire life in the business, having been an active participant in the wonderful development of the industry from its small beginnings to the colossal proportions of to-day. He bore a varied, an extensive, and an honorable part in all its different relations.

Mr. DUNCAN was born in Scotland in 1813, and while yet an infant his father emigrated to this country, and as early as 1820 was engaged in the coal business in Philadelphia, where the deceased found his first employment as a boy in his father's yard. At the age of twenty, he went to Schuylkill County, and was identified with MILNES & HAYWOOD throughout their entire mining career. Subsequently, he went to Philadelphia, and took charge of the Port Richmond shipping-docks, whence he returned to Schuylkill County as weigh-master for the old Schuylkill Canal Company at Mount Carbon. He then engaged in mining operations, whose vicissitudes finally landed him in New York, where he remained in the wholesale coal trade up to the time of his death. Known and respected by all, Mr. DUNCAN filled a conspicuous place among his contemporaries. Without having had the advantages of an academic course, he accumulated a large and varied fund of information. In business, he was conservative and methodical, being governed by the strictest commercial rules, but above all by a strong and unswerving sense of honor. In manner, he was singularly unobtrusive, genial, and kindly; but in argument or maintaining what he thought the right, he was bold and tenacious. His domestic life was a poem. Surrounded by a large and loving family, he sought no diversion outside the sacred circle upon which his whole affection was concentrated, and which he saw bloom into the third generation before he passed away. A man of broad and liberal interpretations, he was of deep religious convictions, and the sweet serenity with which he faced the fell destroyer beautifully illustrated the symmetry of his life.

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. Zinc-Blende and Galena in Pyrites Deposits.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: My attention has been called to a communication written by H. J. Davis, of Charlemont, in your issue of May 19th, 1883, in which he assumes that Mr. Whitmore is in error in making the statement "that on top of pyrites deposits are usually found zinc-blende and galena." I have had the management of the Cotopaxi and Saltiel groups of mines at Cotopaxi, Fremont County, Colorado, since early in 1879, and have found that the large vein of cupriferous pyrites ore running through both properties is covered by a strong vein or seam of zinc-blende, followed on its hanging-wall by a large vein of pyroxene rock bearing galena. The ores are contained in fissures, almost vertical, and have a granite country-rock. In other localities of Colorado, I have noticed the same accompaniments to the deposits of chalco-pyrites. Yours truly,

NEW YORK, July 16. E. H. SALTIEL.

THE OUTLOOK FOR THE LAKE SUPERIOR IRON MINES.

Special Correspondence of the Engineering and Mining Journal.

The iron ore miners of the peninsula have at last awakened to the poignant reflection that, if they wish to send their products to market at all this season, they must begin to make hay while the sun shines. Up to the glorious Fourth, the shipments for 1883 exhibited a falling off of 440,000 tons from the corresponding time of last year, when the total consignments of Marquette and Menominee ores had reached a long mark over a million tons. Of course, it is understood by all that the adequate cause of this falling-off was not any deficit in actual and possible supplies of material, but the cadaverous condition of the market. Producers have listened attentively for invitations to send down their ores ever since the new year opened its eyes; but what little they have heard, with a few trifling exceptions, has been little else than the merest badgering. The highest grades of Bessemer have gone begging. Only yesterday, your correspondent had word from one of the largest rail plants in the West, that no ores need apply in that market. No sales have been made to speak of, outside of concerns which have found it very convenient to offer their wares for what they would bring. It was asserted, early in the season, that the Republic had sold; but the author of the story was color-blind as regards the truth, and that, too, for a purpose. Rumors have often been afloat of large sales, the last being the report that the Cleveland has contracted for the delivery of 90,000 tons, and the Republic for 75,000; but such rumors, as a rule, are simply chewed air. Generally speaking, the mines are as saleless as in January or February, and the hope that is said to spring eternal in the human breast is now turning into the gall of bitterness.

In the mean time, the mines have accepted the grim logic of events by restricting output and curtailing every possible expense. The Republic has lately excused 375 men, and is now working only one shift. The Lake Superior has discharged no less a number, and is doing practically no stoping at all. The Champion has discharged 250 men, and, with the exception of the Barnum, the other mines of the Marquette District, as well as those of the Menominee, have followed a very strong suit. The Champion, I am credibly told, is working but four machines in its whole property. The Milwaukee, of the Negaunee hematites, has closed down rather than pay royalty, and the greater part of the mines are carrying few if any stopes. Some, of course, have not abandoned stoping; but as a rule, these are concerns which must either pump hard or drown altogether. These do not cut any marked figure in our peninsular totals. Several extraneous enterprises, such as the railroad to Copperdom, and the short one from Copperdom to Lac la Belle (the locomotive for which, a heavy Baldwin, passed up last week), have swallowed up considerable of the floating labor; but multitudes of miners, true to their traditions, have drifted into other and distant parts.

Nevertheless, ore has constantly been dropping down to lower ports, despite the stagnant market. It was natural that the Republic should employ its fleet of barges and schooners in transporting its ore. Other mines have had to ship enough to fill their contracts with vessel-owners; and very lately, there seems to be a general suspicion lest a big fish or two should swallow the whole market by being on hand in Cleveland in time of need, and quite a number, therefore, have begun shipping in dead earnest, though the raw material is as yet unsold. This in part accounts for the activity that has been developed in the past two weeks. And yet there is no reason to think that prices for ore will be slaughtered, even though they are deposited in the enemy's country. There will doubtless be sharp competition, and the companies are willing to part with their products at a reasonable margin, the Goliath of Gath having freely offered its specular for $6.50 which sold for $9 last year; but the companies have altogether too stiff a spinal column and too heavy an exchequer for the furnaces to imagine for a moment that they will give their ores away. It is quite probable that a few thousand tons may be sold by shaky companies for what the iron-mongers have a caprice to pay; but this disturbing factor will be transient and of little consequence. The profits of the past will prevent any general collapse approximating to a panic. No one apprehends a collapse here, and those who are best informed are most buoyant. Perhaps a few quotations of ruling prices per ton for ores would be interesting:

Quality ore.	1883.	1882.
No. 1 Bessemer, specular and magnetic.. .	$7.00@$8.00	$9.00@$10.00
No. 1 Non-Bessemer, specular.	5.50@ 6.50	8.00@ 9.00
Bessemer hematites.....	4 75@ 5.25	7.25@ 8 00
Non-Bessemer hematites	4.25@ 5.00	6.00@ 6.50
Menominee ores.....	5.50@ 6.75	7.00@ 8.50

It is quite probable that these figures include the limits of all important sales, if, indeed, any sales thus far can be said to be important, though the lower range of figures is the one for the most part contracted on.

The surface reason why so much unsold ore is now going below is competition between the mines, as already outlined. But there is another reason for sending these large blocks of ore down, which is far deeper. It is: If our peninsula people would retain their lion's share of furnace traffic, they must have their ores within easy reach of the furnace district; and the shipping season is fast wearing away. As it is, the lake mines have always held a strong grip on the steel and iron producers. Of course, it is silly to think that Lake Superior pig will be easily supplanted, or that the furnace-men, remembering past figures which they paid for Republic, for example, will retaliate as soon as any possible opportunity offers itself by letting us up here severely alone. But it remains true that Lake Superior iron men can not afford to be too unconcerned and indifferent, as they would certainly be if they were to hold their immense blocks of ore in their distant stock-piles, because buyers had not been forthcoming in the early months of the year. To keep the ore at home would be to turn the market over in the fall, winter, and spring to the lean producers of Pennsylvania, New Jersey, Vermont, and the South, to say nothing of the West and the new Northwest. And our people might possibly find out that this was a dangerous experiment.

What ought to be done, first of all, is to compute what share our lake properties have in the annual output of our American mines; and after that, ascertain what are the probable limits of demand until another season, and then, by inference, how much ore can be safely sent down this summer from our northern mines. Concerning each of these, it is

only possible to speak with approximate correctness, since many of the data are, for reasons, sequestered. If we follow the advice of Captain Cuttle, however, and "make note of" what significant facts are at hand, we can get bearings sufficiently accurate to outline plans and predict results.

For the past few years, only enough ore has been in furnace-yards during the winter to carry the furnaces over until the opening of navigation, and has been, for this reason, a more or less constant quantity. The product of ore for any year, therefore, may be approximately reckoned by computing the ore requirements of the pig and blooms made in that year, and subtracting therefrom the tons of ore which were supplied by importation. The amount of pig cast in American furnaces during 1881 was 4,641,564 net tons of 2000 pounds. The amount of blooms made directly from ore were insignificant, probably not exceeding 50,000 net tons. Taking into account the lean ores of Eastern and other districts, it is safe to say that the ore required would not fall short of 7,000,000 tons. The importation of ore for 1881 equaled something over 850,000 tons, leaving 6,150,000 tons as the aggregate requisition made upon American mines. To supply this demand, our peninsular mines sent down a round 2,320,000 tons, or a trifle over one third of the whole amount. There are no definite data by which to outline the amounts supplied by other sources, although Mr. Swank gives a few statistics as follows: New Jersey, 737,000 tons; Champlain District, 637,000 tons; Lebanon District, 250,000 tons. During the year 1882, our domestic furnaces turned out 5,178,000 tons of pig and perhaps 50,000 tons of blooms from ore. This could not have been done on less than 8,100,000 tons of ore. Of this amount, some 590,000 tons came from foreigners, leaving 7,500,000 tons to be blasted from domestic mines. To supply this increase, our lake people again came to the front with 2,950,000 tons, or, as in 1881, a trifle over one third of the aggregate domestic supply. Mr. Swank's figures exhibit a like increase in the districts above named, New Jersey furnishing 900,000 tons; Champlain, 675,000; and Lebanon, 400,000.

It is evident, from these figures, that the lion's share of furnace trade has been held by Lake Superior companies. It is evident, moreover, that any encroachment on this lion's share will be firmly held, if it be at all possible, by those who make the encroachment, since the developing of properties, construction of plants, shipping facilities, and the like will give these persons a grip on the market which will be shaken off with supreme difficulty. A period of indifference on the part of lake iron men will place them in the predicament now rattled around in by lake copper men, who, oblivious of the ambitious aspirations of Arizona and Montana miners of black copper ore, held on their course until the Western striplings at last threaten them with ruin. This may be, probably is, a little rhetorical; but yet it contains food for solid reflection. There was no other course for the Michigan mines to pursue than to send down at least enough ore to maintain their hold and influence upon the iron-mongers of the country. A process of restriction, as has already, and in former letters, been set forth, is going on at the mines; but it would be most subversive of self-interest to hold all unsold ore at home, lest, while we are waiting, another's shears clip off the golden fleece. The mine-owners of South Wales, Lancashire, and Cumberland can do what we can not do, since the furnaces which melt their ores are under their very noses, and their mines are never, like ours, locked out of the market by a long and expensive winter. They must not be our examples. We must be a law unto ourselves.

SPECULAR.

A VISIT TO LEADVILLE.

Special Correspondence of the Engineering and Mining Journal.

To the lover of grand and majestic scenery, a journey from Denver to Leadville, via the Denver & Rio Grande Railroad, is a treat not soon to be forgotten. Nothing could be grander than the Grand Cañon of the Arkansas, and no visitor from the East should miss seeing it.

Arriving at Leadville, all was hurry and bustle, and trade was very brisk, as the mines were all making their monthly payment of wages. Harrison avenue is filled every day with busy people, hurrying to and fro; while in the evening, the foot-walks are almost impassable from the crowd of toilers, whose day's work is over and who are out seeking amusement and social intercourse with friends.

Leadville and its surroundings have been so often described that it must be pretty well known now; nevertheless, for the sake of those who may not know, or who may have forgotten, I may say that it lies on a gently sloping plateau, between two gulches, at the foot of the mountains bounding the eastern side of the Arkansas Valley, and about five hundred feet above the river-bed. Around it, to the north, east and south, and within a radius of about five miles, lie the mines which are the chief source of its wealth. To the northeast, about one mile away, is Fryer Hill, containing the celebrated Robert E. Lee mine, the Matchless, Chrysolite, Little Pittsburg, Amie, Little Chief, and several others. Eastward, on the suburbs of the city, is Carbonate Hill, with the Morning and Evening Star mines, the Catalpa, Henriett, Agassiz lease, Gonabrod, Leadville Consolidated, and others upon it. Behind it lies the most celebrated part of the camp at present, namely, Iron Mountain, possessing in its depths the Silver Cord, Iron Silver and leases, A. Y., Iron Hill Consolidated, and other mines, having an output equal to half the total output of the camp. Southeast, and farther away, lie the mines on Printer Boy Hill, famous for the rich ores obtained in the Nellie S. mine; and in the same direction, Breece Hill, Rock Hill, Little Ella Hill, Yankee Hill, and Sugar Loaf Mountain. Southward lies the once rich California Gulch, with its gold diggings, famous in the days of the Pike's Peak rush. Now it is chiefly celebrated as the location of several large smelters, among which are the Harrison Reduction-Works and the La Plata, American, and Arkansas Valley smelters. Such is a sketch of the camp in the immediate neighborhood of the city. I shall now deal with its mines and works more in detail, so as to give a fair conception of its present state.

To begin with Fryer Hill, we find that, although one of its richest mines—the Robert E. Lee—is almost laid off, pending its sale to an English company, its output for the month of June has reached 4604 tons of ore. Among its mines, the Little Pittsburg and the Chrysolite have the largest output, reaching about 900 tons apiece for the month. The Matchless, Little Chief, and Climax Contract put out from 480 to 500 tons. The Robert E. Lee just puts out enough to pay expenses pending the sale. I heard that the Matchless was likely to be bought by the English company which is about to purchase the Robert E. Lee; at least, it has that offer of it. This mine is putting out about 75 tons of ore per day just now, which I was told averaged about 80 ounces of silver to the ton. The owners of the Little Chief, after several offers from parties desirous of leasing their old dumps, decided to make what they could themselves out of them; and to this end have erected four sets of jigs (six to the set) on Big Evans Gulch, which runs just north of Leadville. There they haul all the sand and finer portions of the waste, and concentrate it, sorting out the large by hand at the dumps. It takes about fourteen tons of dump-stuff to yield one ton of salable ore, which will run from 30 to 50 ounces of silver to the ton, although the pieces of galena of which it chiefly consists, by themselves, would run as high as 300 ounces of silver per ton. This leaves a profit to the company of about 25 per cent. In this mine, they have lately run a drift northward on the east line, and have found some small streaks of very rich ore in putting up a sixty-foot rise.

I may remark here, that one of the greatest developments in this camp has, of late, been that of leasing on the part of owners to outsiders. Sometimes, it is a part or the whole of a mine, and sometimes a dump-heap. The above mine, for instance, was offered 10 per cent royalty on its dumps for what it left after washing and sorting. The foreman remarked to me, as he carefully sorted over a handful of waste, that he did not intend to bid against them. The Ætna mine is now leased to no less than four different parties. The owners in this way share the spoils without running any risk.

On Carbonate Hill, the output is somewhat greater, aggregating 5701 tons for June. The Catalpa and the Evening Star both show an output of over 1000 tons, the Morning Star coming near them with 918 tons. The Henriett, Agassiz lease, and Gonabrod yield from 500 to 625 tons. The manager told me that the Henriett mine's present rate of output was from 1000 to 1200 tons per month. The manager of the Leadville Consolidated Mining Company received me very courteously, and informed that the mine was one of the first paying mines discovered. It now holds several contiguous claims. The output is steady at from 300 to 400 tons per month, consisting, like most mines around here, of hard and sand carbonates, which run from 25 to 30 ounces of silver per ton.

I hear that the Clontarf and Brookland mines are soon to be formed into and worked under one company.

Iron Hill, as before mentioned, has the largest output, yielding 17,402 tons, while the total output for the whole camp for June reaches 34,857 tons. The largest producing single mine is the Silver Cord, where I was most courteously received by the manager, Mr. T. S. Wood, who at once proposed that I should go down the mine and see for myself. So, having donned some mining toggery, I descended, and, in charge of the foreman, was shown a part of the mine where they were busiest. No. 3 station contains one of the most magnificent breasts of solid hard carbonate I ever saw. At present, it stands 25 feet by 20 feet of solid ore. In places, it has reached a depth of 60 feet. Here and there, the sparkle of large lumps of rich galena could be seen. Altogether, it was a splendid sight, even for one who was not a shareholder. It was impossible, in the time at my disposal, to visit the other parts of the mine, which runs on an incline 800 feet deep into the hill. I was told that they had struck it quite as rich in other parts. The output runs between 3500 and 4000 tons per month, and the ore contains gold as well as silver, and a considerable quantity of lead. The Iron Silver, with its leases, which has already attracted the attention of the JOURNAL, shows the splendid result of 9700 tons output for June. In this case, to the good fortune of the shareholders and praise of the management, the original mine has had joined to it several other very wealthy contiguous mines. The A. Y. is producing about 50 tons per day, and has now got the new No. 3 shaft down to the mineral; but it is to be put down deeper yet. The Iron Hill Consolidated has an output for June of about 1200 tons, and is doing well. Other mines on this hill are also producing well.

On Breece Hill, the output was about 1250 tons last month, being pretty equally divided among the four principal mines, Breece Iron being at the head with 450 tons, the other three running from 200 to 260 tons.

On Yankee Hill, which has an output for June of 1376 tons, the Robert Emmet yields 1100 tons.

Rock Hill, with the La Plata group as its chief attraction, yields about 1850 tons; the La Plata giving about 1100 tons to this heap. Printer Boy Hill, famous for the Nellie S. mine, which some consider the richest mine in camp, shows an output of 1030 tons, of which the Nellie S. yields 750 tons. It was reported, some time ago, that ore very rich in gold had been struck in this mine; but competent authorities informed me that it was probably only a small quantity, especially as it is common on that hill to find these small pockets of gold ore.

Little Ella Hill yields about 1350 tons to the general quota, most of it coming from the Little Ellen and Opulent mines, which produced respectively 810 and 520 tons of ore last month. The Little Ellen Company is putting in a 110 horse-power hoisting-engine, and will soon have quite a large plant there. Sugar Loaf Mountain adds the insignificant amount of 310 tons from five mines in June, and winds up the list.

In looking at the ore output, one is much struck by its fairly even distribution among the leading mines; for, except in one or two instances, the report shows a wide and comparatively even quantitative output. I venture to think that this is as it ought to be if the camp is to maintain its present prosperity.

Leadville has six large smelters, besides stamp-mills and ore sampling-works. I visited nearly all, and was courteously received by the managers or superintendents. Most of them have from 5000 to 10,000 tons of ore on hand. The Harrison Reduction-Works, which were burned down in May, started two furnaces one month afterward, and are in full blast with all four furnaces now, which speaks well for the energy of the managing officials. Their stoppage largely accounts for the slight disappointment felt in the returns for the last quarter, and for which, considering this, there is really no cause. They run through from 160 to 200 tons per day. The La Plata Works, which have just passed into the hands of an English company, are not contemplating any changes at present, and are working along as usual, running off from 150 to 175 tons per day from their five furnaces. The American Works are putting through about 200 tons per day. The Arkansas Valley Works have lately been undergoing a thorough overhauling; but despite the great and

Digitized by Google

beneficial changes inaugurated during the last three months. have only been obliged to stop twice. for three hours each time. They have put in a new 150 horse-power engine. to take the place of the two smaller ones used until now. It is about the largest in the camp, and will run every thing except the pumps and electric light. Four new boilers have taken the place of the old ones. The new arrangement is very ingenious, and reflects much credit on the management; for of all tests, that is hardest which demands the economical adaptation of new machinery and plans to old works. One furnace is blown out at present for repairs; but when all are going, the works can run through from 200 to 250 tons of ore per day, which is about the largest quantity worked per day in the camp. The Cummings & Finn and Elgin smelters are on the same principle, and are running up to their full capacity just now.

The Leadville Gold and Silver Milling Company is running a large quantity of ore through per day, and shows a good output in silver bars, which are reported 969 fine. The Tabor mill was burned down on May 26th, and is consequently out of the running just now. Up to that date, it had done well. These amalgamators can treat economically a very low-grade ore, lower even than the smelters; but it must not contain lead, whereas, for the smelters, the more lead there is, the better they like it.

In conversation with the manager of four or five mines around here, I learned that it was his opinion that the camp's prospects were excellent for at least the next four years; which, as he said, was as far ahead as any wise man would care to prognosticate. He thought that the bullion output would be greater than ever this year, despite the combined disadvantages of the burning of two works, and the flooding of the mines to such a late period, owing to the quantity of snow which fell this spring, coupled with the late season.

The official statement shows that already the output has reached a total of $8,077,477 for the past half-year, with a total of $4,414,815 for the last quarter. From now until January is by far the best season for output at the camp.

With regard to the surrounding districts, the leading developments are in the Red Cliff, on the Eagle River. and the Robinson district. Both have given promise of a prosperous future. St. Elmo reports big strikes.

Leadville itself is not so prosperous as it was two years ago. In walking about the place, one observes a good many houses to rent or to sell, though chiefly in the back streets. Persons owning property here informed me that they could not obtain what it originally cost them, though these may be isolated cases. As to its prospects, it is difficult to come to any conclusion. Unless fissure-veins can be found in the igneous rocks underneath the stratified rocks, in some of which the ore is at present found, the days of Leadville's present prosperity as a camp are surely numbered. But, on the other hand, there is no saying what effect it may have on the city, if it becomes, as seems very likely, a commercial center for a number of more or less prosperous camps around. These are already rapidly forming, and, it would seem, must naturally depend upon Leadville to a large extent, not only to receive and treat their ores, but as a place from which to draw the necessaries of life. In this way, the future of Leadville may be placed on a much firmer foundation than it has at present. The question must finally drop into the hands of the railroad companies, and it may then furnish a curious example of their power to make or ruin a locality. Anyhow, Leadville's history is already made; for it falls to the lot of few places to record such an enormous output of wealth as $74,000,000 (the output to date) in so short a time. A. C.

LEADVILLE, July 12.

THE LAW AS AFFECTING MINING AND METALLURGICAL INTERESTS.

DECISIONS, RULINGS, ETC.

Loss of Original Papers.—Where there is no adverse claim or protest to a mining application, and the original papers have been lost, the General Land-Office requires no republication of notice of application; but satisfactory evidence of the original publication is necessary, also as to the posting of notice, and that the same remained posted during publication notice.

Suits by Adverse Claimants.—An adverse claimant against an application for patent on a mining claim is required by law to commence a suit. The fact that a suit is pending between the same parties, wherein the adverse claimant is the defendant, does not waive the obligation. (Secretary's decision.)

Relinquishment of Surface Ground.—There is no provision in the mining laws whereby surface ground not in conflict with another claim can be relinquished, and at the same time all the rights pertaining to said surface ground which have been relinquished can be retained by the applicant. Therefore, the relinquishment of surface ground not in conflict with other claims can not be allowed, unless all the rights connected with the lode, and which are covered by said surface ground, are also relinquished. It will be necessary, therefore, for an applicant wishing to retain all the rights acquired by location to make application for all the surface ground not covered by prior locators. If only a small portion is desired, then it will be necessary to be restricted to the right to follow the lode between vertical planes drawn downward through the end-lines of claim. In this case, but not in the other, a new survey will be required. The above decision originated in the following state of facts: A mining company originally stated its claim so as to show on the surface a parallelogram fifteen hundred feet in length by one hundred and fifty feet in width, and at the same time claimed only a portion of the surface ground included within the extreme boundaries of the location. Said portion was divided into three parts: three hundred feet at easterly end, one hundred feet in width; three hundred and fifty feet at westerly end, one hundred and fifty feet in width; and a piece at discovery-shaft twenty-five feet square. The application referred to above was for surface ground twenty feet square at the discovery-shaft. and which it will be perceived is only a very small portion of the surface ground to which the applicants are entitled by location.

Discovery-Shaft in Cross-Lode.—The owner of a lode claim can not sink a discovery-shaft within the space of intersection of a cross-lode claim previously discovered and located.

Coal Land Fees.—The question was asked, Will the government charge a claimant twenty dollars per acre for coal land when the same was situated more than fifteen miles from any completed railroad at the time claimant commenced opening and improving the mine, and at date he filed declaratory statement therefor, but within fifteen miles of which a railroad was completed before said claimant made application to purchase the land covered by said declaratory filing? The Commissioner of the General Land-Office holds that, in the absence of express statutory provision authorizing a disposal of coal lands at a lower price, the language of the coal law requires that if, at the date of "application to the register" to enter coal land, the same shall be within fifteen miles of any completed railroad, payment must be made therefor at not less than twenty dollars per acre, even if a coal mine had been opened and improvements commenced thereon, or declaratory statement filed therefor, prior to the completion of a railroad within fifteen miles of the land.

Forfeiture of Co-Owner's Interest.—Section 2325 of the Revised Statutes prescribes that notice shall be given only "at the expiration of the year" in which the expenditures are made; that forfeiture accrues only upon failure to "contribute a due proportion of the expenditures by each person interested" within ninety days after service of personal notice in writing or within ninety days after the expiration of the period of publication. Will it prevent a forfeiture of "a co-owner's interest if he performs his portion of the expenditures after the necessary expenditures have been made by his co-claimant"? The above is the substance of several queries, propounded by a party in interest, to the Commissioner of the General Land-Office. He replies that, after publication of notice, the delinquent is bound to "contribute" his proper proportion, that is, to reimburse his co-claimants. But if a part of the co-owners have made all the required expenditures before the expiration of the period within which the law requires that they shall be made, the question whether the other claimants may make additional expenditures upon the claim equivalent to their proper proportion, instead of reimbursing their co-claimants, is a matter in which the commissioner is in doubt, and prefers to express no opinion upon the subject except in the event of a case of the kind coming before him, when he may be assisted by argument or guided by precedents established by the courts.

Claims upon Reservations.—Title can not legally be initiated to public lands reserved by the government from sale or other disposition, nor to lands erroneously excluded from a reservation by mistake of a surveyor. Location of claims upon reserved lands being void *ab initio*, the Commissioner of the General Land-Office has no authority to recognize locations made prior to the opening of such reserved lands to exploration and entry, as entitling locators to the preference right of purchase after the restrictions have been removed. Contests arising out of the circumstances indicated, between parties claiming by adverse locations, must be adjudicated by the courts. In the above case, mining claims were surveyed in a reservation through an error of the surveyor.

THE PRODUCTION OF QUICKSILVER IN CALIFORNIA.

Mr. J. B. Randol, of the New Almaden mines, has kindly favored us with the following interesting table:

PRODUCTION OF QUICKSILVER IN CALIFORNIA FOR TWELVE MONTHS ENDED JUNE 30TH, 1883

MONTHS.	Napa.	Great Western.	Sulphur Bank.	Redington.	Great Eastern.	New Idria.	Various.	Total (flasks).	New Almaden.	Grand total (flasks).
1882.										
July	380	410	579	195	111	169	15	1,859	2,522	4,381
August	582	490	418	184	388	130	61	2,253	2,432	4,685
September	641	513	430	225	348	129	157	2,443	2,766	5,209
October	580	516	370	251	229	266	73	2,285	2,844	5,129

A NEW SMOKE-CONSUMING DEVICE.—The Illinois Central Railroad Company is endeavoring to secure a smoke-consumer attachment to its locomotives that will enable it to comply with the Chicago ordinance. For two or three weeks, the engine Robert L. Walker was running on the company's tracks along the lake front at Chicago. It was built at the Taunton (Mass.) Locomotive-Works, and has cylinders seventeen inches in diameter and of twenty-four inches stroke. It contains a smokeless furnace, invented by Mr. Robert L. Walker, of Boston, for whom the engine was built, and who brought it to Chicago in order to demonstrate to railroad men and others interested that he can effectually do away with the smoke and spark nuisance. A vertical water-table divides the fire-box or furnace into two compartments, one of which is charged with fresh coal, while the other contains freely burning coal. The compartment containing the fresh coal is closed at the top by a damper which confines the gases and is regulated by the fireman in the engine-cab. The smoke and gases arising from the fresh coal as it becomes heated, pass through a small opening over the water-tables and above the fire into the next compartment, where they are entirely consumed. The operation is then reversed by the other compartment of the fire-box being charged with fresh coal, in consequence of which the smoke and gases pass into the compartment opposite, where the fire has reached a high temperature. Any sparks escaping through the flue in front of the engine are arrested by an extended fire-box, also in front of the engine. There is in the fire-box a fire-brick arch, which becomes highly heated, and preserves a uniform temperature in the furnace and assists in consuming the gases from the fresh coal. A recent practical test in pulling heavily laden trains showed that neither smoke nor sparks were emitted from the smoke-stack.

THE MINING REGION AROUND PRESCOTT, ARIZONA.*

By John F. Blandy, Prescott, Arizona.

WITH SUPPLEMENT.

With the Report of Mining Statistics for the year 1872 there was published a geological map of the United States and Territories. This is, I believe, the only map which represents the geology of Arizona, and is, as far as my observations go, correct. It is, however, on so small a scale as to be of little practical value to the miner. I know of no other maps, even of localities, of this territory. The topographical maps are also on so small a scale as not even to serve as guides from place to place; the largest, that of Eckhoff and Ricker, being only 30 by 30 inches to represent a territory of 135,000 square miles. For these reasons, it is exceedingly difficult to describe the various mining centers in an intelligent manner, and equally so to examine such a hilly country as it is intended to describe in this paper.

When I first came into this territory, I soon realized the troubles I had to encounter in trying to form an opinion, or even to get the needed information on the geological contour. I have, therefore, labored as best I could to get a topographical diagram of the section of country represented by the map which accompanies this paper.†

The lines run by the Land Department up the valleys of the Aqua Frio, and those west of the Hassayampa, and connected east and west to the north of Prescott, enable me to correctly inclose the space covered by the Bradshaw and Sierra Prieta mountain groups; but the territory covered by these mountains, and the most difficult part, I have had to fill up as best I could. I have met with such success as to meet the approbation of those most familiar with the country, and, with the map in hand, any one would be able to cross it in any direction. As there has not been a single line of survey made across it, this has been no small undertaking, and I have had to depend upon sights from prominent points with the pocket-compass, or, in the absence of that, to make observations, with watch in hand, and guess as nearly as possible the meridian direction. But one main wagon-road passes through the district, that from Prescott to the Peck mine.

Having constructed a map with approximate correctness, it remains to mark in the general geology; but it is still difficult to draw accurately the distinct lines of junction between the formations. To do this requires an amount of muscular exertion that no one can understand unless he has tried it in such a hill-country—a region of gulches and steep, rocky hillsides, most of it covered with a growth of tangled thorny bushes, or prickly, poisonous cactus plants.

I have, therefore, only marked the general run of the rocks, without attempting the line of the boundaries of any. It is only meant as a skeleton upon which others may assist in filling in the detail as they may be able. It is the detailed geology of a region which is of the most assistance to the miner, and it can not be too minute. I am not aware that any geological map has been issued of any locality of Arizona.

I shall refer only to that part of the map which shows the country between the Peck mine and the town of Prescott. The Peck mine is situated in a primary slate formation, the north boundary of which is at Bear Run. This sweeps around in a northerly direction, crossing Turkey Creek and the mouth of Wolf Creek, the head of Cedar Creek, and after crossing the Big Bug Creek to the north of the station, passes northward by the Silver Belt mine, and is lost to view under the Aqua Frio flats and Lonesome Valley, or what is marked on the government maps as the Prescott Plains.

To the north of this formation, we have a porphyritic-granite ridge, passing from the Tuscumbia mine through to Trinity, crossing Turkey Creek at the mouth of Pine Creek, thence over the high divide between Pine and Wolf creeks. This does not show itself at Big Bug Creek, unless the small field of granite near Boggs be a continuation of the same. Next north of this granite ridge, we have a syenitic gneiss, covering the country up to the foot of Mount Union, with the exception of a narrow belt of hornblende slate, which crosses Turkey Creek at the Masterson mill. This brings us to the great granite center of Mount Union. From its sides start out the various streams of Main and East Hassayampa, Turkey, Big Bug, and Lynx creeks. Mount Union is said to be the highest peak, with the exception of San Francisco Mountain, in Yavapai County, which would make it about 10,000 feet above tide. It, with two neighboring peaks, the one to the north, the other to the south, appears more like a north and south ridge of granite, and throws out a finger forming the dividing ridge between the Big Bug and Lynx creeks, reaching nearly to the Silver Belt mine, where it abuts against the high-tilted slates of the first-mentioned formation. Another finger is thrown out to the southwestward, forming the divide between the East Hassayampa and Turkey Creek, the highest point of which lies between the Bodie and Bully Bueno mines. At the point where the Peck road crosses this divide, at the lowest point, it is hidden by a thin covering of the syenitic gneiss. Between Big Bug Creek and the head of Wolf Creek, lies a high plateau called the Mesa. This is a sheet of "malpais," or lava, from fifty to one hundred feet or more in thickness, which rests upon the vertical strata of the syenitic gneiss. The valley of Lynx Creek is occupied by a more or less stratified granitic rock, which extends southward across the head of Hassayampa, and beyond the Senator mine. This is separated from the large field of granite which surrounds Prescott by the ridge of hornblende schists which crosses the Hassayampa at the bridge, and forms a divide between it and Lynx Creek, and in which heads the North Wolf, Groom, and Granite creeks, the highest point of which is Spruce Mountain.

The Prescott granite, extending northward to the great mass of Granite Mountain, here and there incloses patches of hornblende slates, and syenitic gneiss, and is intersected by trap dikes and protrusions of columnar basalt. Of the latter, two fine examples are to be seen near the town—Thumb Butte, and a hill near the mouth of Banning Creek. To the north of Prescott, on the east side of Granite Creek, may be seen the syenitic gneiss which underlies the county eastward to lower Lynx Creek. We now have a general outline of the geology of the space lying between the Peck mine and Prescott. I have seen too little of that lying to the westward, or of that lying to the east of the Aqua Frio, to refer to it at present. It only remains to make some reference to the veins occurring in the various formations.

The large majority of these, whether in the stratified rocks or in the granite, have a northward and southward trend, varying, say, from N. 20 degrees E., and S. 20 degrees W. to N. 20 degrees W., and S. 20 degrees E. The exceptions do not vary greatly from this, although I have noticed a few that have a nearly east and west course. Among the stratified rocks, a large number are what might be called "*layer*" veins; that is, they strike and dip with the formation, and are limited in length, seldom extending for more than three or four mining claims. In many instances, I have supposed these to be formed by the warping of the strata, causing openings to be made between the strata. This is particularly the case where the white quartz ledges occur, as in the belt in which are the Bully Bueno, Yaho, and the gold ledges on Pine Creek.

The veins in the slate formation of the Peck District occur in or in contact with heavy quartz strata, locally called quartz dikes, and carry silver in form of chlorides, sulphides, and in galena. In some of the veins, large amounts of carbonate of iron occur. The quartz dikes are the conspicuous feature of the district, standing like high walls, sometimes as much as fifty feet above the slates. The finest examples of these walls can be seen near the mouth of Wolf Creek, where they occur not more than six feet thick at the base, and stand at least fifty feet high, terminating in pinnacles—a fair representation also of the dip of the strata.

The veins in the granite ridge next north seem to occur in groups, as in Tuscumbia, Trinity, and on the east slope of the Wolf Creek ridge. In these, the ores are also silver-bearing, in form of chlorides with lead, brittle silver ores, and in galena and blende. The principal vein-matter is quartz and barytes.

In the syenitic gneiss region, the veins are all silver-bearing with the exception of the belt referred to above, which passes through from the Bully Bueno mine across Pine and Wolf creeks, which are gold-bearing quartz veins. Between this belt and the granite on the south, the ores are much the same in nature as those of the granite, with the exception that there is but little antimony in combination. The vein-stones are the same. To the north of the gold belt, up to the foot of the Mount Union granite, the amount of galena in the vein increases in quantity as you go northward, until finally argentiferous galena with much pyrites is almost the only ore. The barytes also become less and less, and quartz increases in quantity. In this section, I have found the only lime spar, in form of nail-head, that I have seen in this region. This occurs in the Goodwin vein.

The veins in the Mount Union granite are all gold-bearing, many of them also carrying silver in combination with galena, and large amounts of pyrites. The gold in the croppings of the veins and to a limited depth, is free, but below altogether in the pyrites. Some veins are found containing large amounts of carbonates of lead which yield well in silver. The decomposition of these veins and of those in Lynx Creek Valley is the source which has supplied the gold to the placers in all the streams heading in this mountain, more particularly to the Hassayampa and Lynx creeks. In some of the veins of this formation, is to be found much blende of a very dark character.

The veins of the Lynx Creek Valley are, as a rule, the largest of the region, varying in width from two to twenty or thirty feet. They carry gold and silver in varying quantities. Sometimes, pockets are met with yielding at the rate of several hundred dollars per ton in gold. The occurrence of silver is much more uniform. Most of these veins have been prospected largely in the cropping and the ore worked in arrastras. This has been, however, to a limited depth, I believe never over thirty feet, and most of them much less, as the baser ores occur, and the miners have had no means of treating them.

Below the decomposed croppings, the ores are the basest of the region, being a mixture, in every conceivable variation, of sulphurets of iron, zinc, antimony, lead, and copper. Of course, all are not equally contaminated, as in some pyrites form the mass of the ore; in others, but little copper is to be seen. As a rule, it may be said that the ores will average some sixty dollars per ton in the precious metals. This district is generally regarded as the gold section of the region. The prevailing vein-stone is quartz and decomposed wall-rock. The only rare minerals I have heard of as recurring in these veins are molybdates and phosphates of lead in the Accidental mine, but I have seen none.

The veins of the hornblende schist range are gold and silver-bearing apparently in about equal quantities. The silver occurs as chloride, and also in galena, many very rich and large specimens of the former (horn-silver) having been found. In some of the veins, very rich streaks of gold have been encountered by the prospectors. Much of the vein material is of a talcose slaty nature near the walls, and the ore-streak is largely made up in many of the veins of a very flinty yellowish-brown massive quartz; this is particularly the case where galena occurs in the vein. But few veins, and hardly any of note, have been opened in the Prescott granite. On the southern edge of it, along the Hassayampa, some strong veins of gold-bearing pyrites have been opened; a strong galena vein, with a small amount of pyrites and a large vein of copper pyrites, have been developed to some extent.

To this meager description of the region I might add that a band of porphyritic slate extends on the east side of the Aqua Frio from the Homestake mine at the western foot of the Black Hills southward to Copper Mountain. Whether this formation lies next east to the slates of the Peck District or not, I can not tell, not having closely examined it. So far as examined, these porphyritic slates show veins of copper ore of high grade, containing silver in greater or less quantities from $7 to $85 per ton.

On the map, I have marked approximately the sections covered with timber. This consists of pine, oak, and juniper.

The streams called creeks, for want of a better name, might more properly be called *sluice-ways* to carry off the heavy falls of water in the rainy season. There is, however, a small amount of running water in all of them for most of the year, particularly in the winter and spring, caused by the melting of the snows.

As I have said, this is but a meager description of the geology of a large and important mineral district; but I have meant it only as a

* A paper read before the American Institute of Mining Engineers.

† The engraved map accompanying this paper is one half the scale of the original map.—ED.

Digitized by Google

beginning by furnishing an outline of the district and giving an opportunity for others to assist in building upon the foundation which is thus begun.

It will be understood that the mineral district extends much beyond that part which I have attempted to describe. It reaches southeastward to the Tip Top mine region, the copper deposits of Castle Creek, the Tiger District, and southwestward to the Vulture mine, near Wickenburg, and the gold mine of Antelope Peak; westward, to include the copper mines in Copper Basin; and on the east, it covers the copper and silver mines of the Black Hills and Ash Creek, and the gold region of Cherry Creek near the Verde. To these may be added the gold mines and placers of the Black Cañon and Squaw Creek.

This region possesses as fine a climate as can be found in the United States, fine open weather in winter, with but few storms, and those of snow. The nights, from November to April, are cold, although the days may be clear and balmy. In summer, although the thermometer may register from 105 degrees to 110 degrees in the shade, the atmosphere is by no means as oppressive as in the Atlantic States at from 85 degrees to 90 degrees. There are very few days in the year when it is too disagreeable to work in the open air. Many severe things have been said of "dry Arizona;" but it has never been called the "land of beautiful and glorious sunshine," to which it is entitled.

ON THE OCCURRENCE OF GOLD IN WILLIAMSON COUNTY, TEXAS.*

By Prof. Charles A. Schaeffer, Cornell University, Ithaca, New York.

In the early part of last year, I received a small amount of powdered mineral from Williamson County, Texas, to be examined for silver. The specimen proved to be limestone, slightly colored by hydrated oxide of iron, and assayed, per ton, $2521 in gold and $5 in silver. Supposing, of course, that this was a case of "salt," I applied for more of the material, stipulating that it be sent in lumps, and received several pieces, averaging from three to four cubic inches, which assayed $46.50 in gold. A third lot, about one peck in amount, consisting entirely of good-sized lumps, assayed $160.19. Frequently-repeated examinations of the lumps from the second and third lots convinced me finally that, in those cases, at least, the material had *not* been tampered with, and that the gold had been deposited there by natural agencies.

In the month of April, I visited the point from which the specimens were said to have been taken, about twenty miles north of Georgetown, and from an old shaft, about 15 feet deep, took a number of samples. At the very top of the shaft, there is a hard cap-rock, four feet thick, and below, extending through a thickness of about 2½ feet, is a bed of very porous rock, highly colored at many points with hydrated oxide of iron. Below this is a layer of very finely granular limestone, of a faint pinkish color, about six feet thick, and, still lower, another bed of porous rock from two to three feet thick. The samples previously sent me corresponded exactly in appearance with the rock in the two porous beds. Subsequent examination of fourteen samples taken by myself gave the following results: Three contained no gold, four showed a trace, and seven contained amounts varying from $2 to $20.67 per ton, the average of the fourteen being $5.46. These results, though low, nevertheless showed the existence of some gold, and it was therefore deemed advisable to investigate the subject more thoroughly. In the month of June, I revisited the place, and spent several weeks in prospecting the neighborhood.

Extending through Williamson County from north to south, covering a breadth of from four to nine miles, are a number of long, low hills, generally from fifty to a hundred feet above the surrounding prairies. Near the top of one of these ridges, was the shaft previously referred to. The rock was all horizontally stratified, and there was no evidence or probability of any vein. If gold was present in paying quantities, it would undoubtedly be found in the beds of porous rock. To test the permanency of the existence of gold, seven shafts were sunk at various points around the original shaft, and at distances varying from one hundred to three hundred feet. In all of these, the porous strata were encountered, and, so far as the external appearance of the rock was concerned, it was found to be precisely the same as in the first shaft, although the thickness of the beds varied somewhat at different points. Fifty-two specimens taken from the various points where the porous strata had been exposed, and from the outcroppings of the same, gave the following results: Twenty contained no gold, and thirty-two contained amounts varying from $1 up to $231.50, the whole fifty-two averaging $15.20.

Further investigation convinced me that, although these results were apparently highly favorable, nevertheless the average of the whole rock is far below the figures indicated. Selecting from all the points worked thirty-two lots, they were all carefully sampled and the samples assayed. Of these samples, thirty-one contained no gold, and one contained $1 per ton. The examination of the dirt taken from the dry beds of the ravines, below the level of the two beds in question, showed sometimes one or two very minute colors, but more generally nothing at all. While, therefore, not desiring to call attention to this locality as a possible source of supply of gold, I nevertheless wish to record the fact that gold does occur at the point in question in moderate amounts.

The most remarkable feature of the occurrence is the fact that the limestone is undoubtedly Cretaceous. It is generally stated that gold may occur in rocks of all ages, and Professor Kerr, in a recent paper read before the Institute,† concludes with these words: "From the facts here given, it would seem that gold is so widely diffused that we may expect to find it in any kind of rock." Nevertheless, I believe the occurrence of gold in Cretaceous limestone has not as yet been reported in the United States.

As regards the mode of deposition, it is very evident that it got into the rock in the condition of auriferous iron pyrites. The calcium sulphate, resulting from the decomposition of the pyrites and the limestone, has all been washed out, occasioning the porous character of the rock, and the greater part of the brown oxide of iron and the insoluble gold remain entangled in the pores and crevices. At some points, the gold has been concentrated by the action of water, while in others it is entirely absent. Unfortunately, there is no way to distinguish between the auriferous material and that which is entirely barren, since the amount of the oxide of iron seems to bear no relation to that of the gold present.

There is a tradition, very commonly believed in the neighborhood, that, two or three hundred years ago, the Mexicans obtained silver there, and, in proof of this, attention is called to a large number of irregular trenches to be found at many points on the hills. These trenches have, with the lapse of time, become partially filled, but in all cases they are easily identified by the large blocks of the hard cap-rock which are strewn around on both sides and in the trench itself. So far as silver is concerned, the popular idea is clearly a mistaken one; but it would seem not improbable that, in the days of cheap peon labor, this district may have been worked for the small amount of gold to be found.

AMERICAN MINES IN THE ENGLISH MARKET.

Mr. William Weston has written one of his vigorous letters to the London *Mining Journal*, which so forcibly deals with questions frequently discussed in this country that we make room for the following abstracts from it:

For those who wish to buy developed mines which are now actually paying, there are plenty of them in San Juan. I have often heard it said in London, "If the Americans have any good mines, they keep them; but if they have any worthless ones, they come over here to unload." That they "keep them" is not true, as no man will sell quicker at a fair price than an American. There are thousands of good mines and prospects in Colorado for sale, and an Englishman's money is just as good to the owners as that of their own countrymen, so the first part of the wise saw is bosh. That a great many worthless American mines have been brought to London I admit; but if they found purchasers there, who have the buyers to blame but themselves? No man is so generally skeptical of every thing American as the astute Britisher; and no man, when he does buy any thing American, does so with such utter folly, as a rule, as that same gentleman. He exercises far less care than he would if buying a horse, and in most cases buys it through the medium of three or four different lots of middle-men, and naturally pays four times as much as if he bought it from the owner, as those modest and obliging mediums generally expect to realize out of the transaction quite as much as the owner receives for his property. Then, when the buyer finds he has been sold, he declines to admit his own folly, and raises a hue and cry against Americans and their mines in general. Just about as mean and cowardly as the man who goes into a gambling-den with the intention of winning the gambler's money; but when, instead, the gambler wins his, he calls on the police to help him get it back again.

Now, I will explain why it is that so few really rich American mines find their way into the English market, and I can best do this by telling how some of the best dividend-paying mines have been placed on the American market. I will mention names of neither men nor mines, to avoid the suspicion of surreptitious "puffing." There is in America a firm of two gentlemen, said to be worth fifty millions of dollars, which they have made legitimately in their business, which is what I call being "jobbers in mines." They have a staff of trusted experts; and when they hear of an exceptionally rich mine or prospect, they send one of these men to examine, with power to write a check for it on the spot if necessary.

Having bought it, they then proceed to develop it thoroughly, by creating large reserves of ores, erecting pumping, hoisting, and reducing machinery, thus bringing the mine into a permanently paying condition. Then, and not till then, do they organize a company, and offer the shares to the public, and the public takes the mine readily, paying this firm, of course, a very handsome profit, which, as they have had all the risk, they are thoroughly entitled to. As long as the public gets good value for its money, and a mine that pays good dividends, they neither ask nor care how much profit the vendors make out of it. And it must be remembered that this firm, although they rarely do make a mistake, are not infallible; sometimes a mine turns out badly, and then, as they do not offer it to the public, they lose all they have paid for it, or put into development.

On the other hand, how do the English get hold of American mining properties? Chiefly from the hands of middle-men, who are generally penniless adventurers, who get hold of a bond or option on some mine for such length of time as will enable them to get up a company, advertise the shares, and so get the money to pay for the property and their own commission; the bringing of the mine into a paying condition being quite an after-consideration, and one which these gentlemen care nothing about. And I assert, as a positive fact, that the owners of really good mines in Colorado will not tie their property up or have it hawked about London by adventurers. I do not mean to say that all properties that come to the public through middle-men are worthless by any means, as some of them are very good, and as the purchasers are put into communication with the owners and the property reported on by reliable English engineers, every thing is square and above-board. To show why some rich mines never find their way to London, I will cite a case in point. I know a mining property in the San Juan region, near Ouray; fair claims on the same vein all in pay, the ore yielding from 50 ounces to 500 ounces of silver and 10 ounces of gold per ton of 2000 pounds; price, £150,000 cash, with fully that amount of ore (gross) in sight; title perfect; true fissure-veins; and total length of claims along the course of the vein 6000 feet. The owners of this group are the original discoverers, and will not tie their property up to any one for six months, in order to give them a chance to sell it. Why should they? The dead-work alone has more than paid all expenses; and if they want some money, they can take it out of their mine. There is the property for sale at a price, and the owners are content to bide their time, knowing that, sooner or later, a buyer will come along and pay them cash for it. Therefore, they have no inclination to tie it up for six months, in order to let some middle-man or promoter of companies take it to England and try to sell it. And as no middle-man will take the trouble to try and sell it in England without a firm option, the property does not find its way there. On the other hand, owners of worthless properties

Digitized by Google

which they can not sell themselves will readily give an adventurer a bond or option on the property, and take the chances of his being able to sell it.

Owners of rich properties like the one I have named will give a bond or firm option if they are paid for—that is, if a certain sum be paid down, that sum to be applied on the purchase money if the sale is consummated, or forfeited if it is not; but those as a rule who play the role of middlemen have no money to pay for any thing.

From the foregoing, it will perhaps be understood why so many poor properties go to England. To reiterate. No owner of a really rich paying property or promising prospect in Colorado will tie his mine up to a party of middle-men for six months, in order to give them the chance of getting the money to pay for it, unless he gets a sum paid down as forfeit-money, or unless he happens to be very well off, and have a great deal of mining property to dispose of, and I know of such exceptions now offered in London, and very good properties they are. If a few wealthy Englishmen would do as the firm of American jobbers before mentioned—come to San Juan and see the mines themselves, or send their engineer to examine, with power to write a check if the property proves as represented, they would get some of the richest gold and silver mines in the world, and at reasonable figures. It will be asked, perhaps, "If these men own such good gold mines, why do they wish to sell them?" But no miner or man who knows any thing about mines will ask such a question. Most of our richest mines and prospects in San Juan are still held by the original discoverers—poor men. Every miner knows that it takes large expenditures of capital to put a silver or gold mine into permanent pay. By this I mean creating reserves of ore at least two years ahead, erecting pumping and hoisting machinery and reduction-works to treat the ore. If they take ore out of their mine without doing this, I call it "picking the eyes out" of their mine, and no good miner will do it. In San Juan, we have a number of phenomenally rich silver mines, which have paid from the grass-roots; but because they will do this, it is no reason why they should have their eyes picked out; on the contrary, they are the very ones that deserve the greatest care and the most systematic development.

In one claim of the group of four already cited, there is ore in sight to the value of half a million dollars—ore actually blocked out, and I have heard it said: "Instead of selling their mine for £60,000, why do not the owners go to work and take it out of the mine?" Simply because they are not fools. The ore already blocked out is above water-line, and this taken out, they would have to erect pumping and hoisting machinery to go deeper. More than this, as they have no capital to erect reduction-works, they would have to sell the ore to local buyers at a large sacrifice of profit; then, again, it would take some years to mine it without any capital. So, as the owners have other mining property to develop, and as the country is rich and new, and plenty more mines to be found, they prefer to stick to their legitimate business of prospectors—that is, finding and selling mines. They prefer, in fact, rather to take a reasonable sum, cash down, for their mine, and sell to men who can afford to develop it into permanent pay, than to "pick its eyes out," wait two or three years for their money, and then, perhaps, have a white elephant on their hands in the shape of a rich mine, without the capital to enable them to get the ore out any deeper.

THE PRODUCTION AND UTILIZATION OF GASEOUS FUEL IN THE IRON MANUFACTURE.*

By W. S. Sutherland.

(*Concluded from page 22.*)

In the first part of my paper, it is pointed out that, to insure sound welding, the gas should be supplied with the requisite air in constant and definite proportions. To secure this, it has been found necessary to mix the gas and air thoroughly together before combustion, care being taken to prevent explosions, and dissipate them if they should happen. A very powerful and concentrated flame is thus secured, which, when it contains an excess of gas, has no tendency to oxidize the iron, and gives a very soft, mellow heat. I do not believe that mixed gas and air have ever been worked in this way before—at any rate, not on the large scale that we work on—and, as must generally be the case in new combinations or methods, the study of its action must be instructive. Explosions of the mixed gas and air are prevented by very simple means, and the method has now been at work for some ten years without accident. I should like, in this connection, to mention that, when an explosion occurs in any ordinary working mixture, it does not instantaneously travel along the mains, but is carried forward in the form of a wave or disk of flame, traveling with a certain velocity. This disk seems to have some dynamic properties which liken it to a solid mass in motion. Thus, it will not turn a corner readily unless obliged to do so, and strikes any thing it comes against with great force. If, then, at a convenient corner of the mains, an outlet be provided in the direction of the delivering main, and a light cover of India rubber be fastened on, the disk of fire will cut it out or break it, just as a blow would do, and no further damage is done. Indeed, I have often watched this disk of fire moving backward and forward in a passage, and obeying the hand that was closing and opening the gas and air-valve. The ordinary Bunsen burner, in which the gas and air mix as they come together for combustion, is always supposed to produce a higher temperature; and since by the above system a far more perfect mixture and diffusion can be obtained, it naturally occurred to me that this offered an easy solution of the problem of obtaining high temperatures. And so it does, but coupled, I must confess, with some drawbacks. I have spent much time and trouble over it, and argued in this way: If it be possible to keep down the carbonic acid in producer gas, while at the same time storing up in it nearly the whole of the thirty per cent of heat before mentioned, and if by mixing the gas with the proper amount of air before burning a rapid combustion be effected, why could not this simple means be employed to burn fuel generally? And if it be true that mixing the gas and air raises the temperature, this increase could only be at the expense of the outgoing gases; therefore a kind of regenerative action should be set up that would cause an accumulation of heat at the root of the flame, and which would extend itself as the action went on.

Now, I must say, and can show in practice, that all this is true; but so far, its application seems to be limited to special uses, of which steam-raising is one of the chief. Consider that by this means the full effect of the fuel can be produced directly it enters the boiler, so that complete combustion is secured at once, and the gases have only to give up their heat in passing along the boiler; that the highest temperature is produced at the very first; and that there is therefore a greater fall and consequent better duty, and you will then say that there is reason in what I say. But in these general uses where Dr. Siemens has introduced his magnificent system of regenerators, experience has so far shown that his system is better, and for the following reasons: Suppose a stream of mixed gas and air to enter a furnace. There is no trouble about diffusion, since the gas and air are already thoroughly mixed, and therefore they ought at once to burn and give out their highest temperature; and since the rate at which the gases will conduct depends upon the temperature of the heating body (the initial heat of the gases being supposed constant), and as well upon the thickness of the stream of gas, it follows that if this higher temperature be produced quickly, and the stream of gas be kept thin as it enters the furnace, more heat should flow back into the hinder layers of the gas while those in front burn, and that thus the reaction would tend to accumulate heat at the root of the flame in precisely the same way as in a coal fire, so that the faster the gases are driven into the furnace the greater the temperature would become. Now, all this really happens; but in a coal fire the fuel is traveling back, carrying heat with it, which is not the case in the gas fire, and this has to be allowed for. Besides this, the rule of conduction in the gases must be within certain limits of proportion to the speed with which the frame travels back, so that to get the highest temperatures with good producer gas, the flame must be made to envelop to some extent the stream of incoming gases, in order to make it as hot as possible all around, and this stream must also be made very thin. All this is exceedingly difficult to manage. Sometimes all goes well, a great wave of heat can be seen accumulated round the tuyere, and the furnace is hot directly; but the next minute, without any change in the quality of the gas mixture, the wave of heat is blown away from the tuyere, and in a moment or two the furnace goes down. Still, this system can be used in many ways where regeneration is not applicable, as in steam-raising and in chemical works, and wherever a very high temperature is not desirable, although, for economical reasons, it is better in most cases to get the highest temperature attainable. It is not easy to understand how the rise of temperature tends to extend over the remoter parts of the furnace; but heat always tends to flow from the hotter to the colder parts, as is well known, and the heat in a furnace may be compared to a mound or wave of water on a stream driven over an eminence which remains stationary while the water goes on. The higher temperature gradually spreads more or less in the furnace, without at all breaking the law of conservation of energy, the increase of heat being always obtained at the cost of the waste gases.

Ten years' experience with thoroughly mixed gases has tended to confirm the timid views advanced some years ago. These observations refer to the action of the different gases and mixtures of gases and air upon iron and steel in welding and heating, and in puddling iron as well, in which direction some experience has been gained with them.

In a paper read before the Royal Society, Professor Graham showed that iron at an elevated temperature is permeable by both hydrogen and carbonic oxide, and especially so by the latter gas, and he added that in the process of manufacture soft iron absorbed or occluded within it a considerable volume of carbonic oxide, "which it carried about ever after." Now, in treating iron or steel, the only general fuels we have are carbon and hydrogen and compounds of them, which are all burnt with oxygen. The iron is practically always oxidized when in the ore; but after treatment in the blast-furnace, it contains more or less carbon; and leaving out silicon, sulphur, phosphorus, and other impurities, the metal varies almost indefinitely between pig-iron and ore, becoming white iron, cinder iron, cast-iron, steel, soft steel, wrought-iron, pure iron, and burnt iron containing oxygen. Therefore, if there be no impurities in the iron beyond hydrogen, oxygen, and carbon, all these different qualities would be owing to some difference in the relative quantities of these substances in the iron, to the manner in which they are combined or mixed, and to the different states in which they and the iron may be. In treating iron for welding by the aid of mixed gases and air, it is found that the first essential is, that there be an excess of gas in the mixture. The slightest excess of air, of fully combined carbonic acid, or steam infallibly burns the iron, makes it rotten and the weld becomes a bad one. If pure hydrogen in excess be used, it is difficult to weld with it. A higher temperature is required, the iron appears to remain hard up to the melting-point, holes are easily eaten into it, and when broken the iron will be found to have a fine white crystalline fracture. The weld is strong, but very short, as in steel. If carbon be the fuel used, the weld varies from a coarse, steely fracture, to a ductile one, and sometimes a rotten one, according as the carbon or air is in excess. If carbonic oxide in excess be used, the iron begins to soften at a lower temperature, becomes pasty, and seems to effervesce; when welded, it is very tough, and breaks with a tough, dark, silky fracture characteristic of wrought-iron. If soft steel be welded, it will not bear the same degree of heat that wrought-iron will, but tends to fall to pieces on the hearth; when welded with a good carbonic oxide flame, however, it works very well, and stands a good elongation before breaking.

From observation of these facts, I always endeavor to get as much carbonic oxide as possible in my gas, and as little hydrogen and oxygen as I can, consistently with obtaining the requisite temperature. Pure iron can only be regarded as a chemical curiosity, which may for a moment be produced in practice, but which passes at once to wrought-iron or oxidized iron. Now, in making steel in the Bessemer converter, the metal is heated with air until all the carbon is blown out; and if the process could be stopped at exactly the right place just when the carbon had all become carbonic oxide and remained in the metal, undoubtedly a soft, ductile metal just like wrought-iron might be produced without having to add any spiegel. But so long as any unoxidized carbon remains in the iron, I say from experience it would work "raw," as the welder says, when welded, and would be crystalline; and if iron oxide remained

* A paper read before the British Iron and Steel Institute.

Digitized by Google

in it, it would be rotten. Now, why should we not recognize Professor Graham's definition, and say that while steel is iron containing unoxidized carbon, wrought-iron is iron in which carbonic oxide is occluded, taking the intermediate place between carbon in steel and oxygen in burnt iron? Carbon and carbonic oxide are both soluble in iron, while carbonic acid and oxygen are both practically insoluble, but a low oxide of iron is again soluble. It seems reasonable to imagine that carbonic oxide, which must be fluid in the metal, acts the part of a solvent in allowing a proper coming together of the particles, while carbonic acid and oxygen tend to keep them apart, and iron oxide, while somewhat soluble, acts the part of carbon in pig-iron in an exaggerated degree, in that it causes the metal to become softer, and even rotten, when cold. A curve might be drawn showing the transition from one state to another, in which the admission of carbonic oxide would lengthen out the point representing pure iron. Now, the conclusion I wish to draw from all this—if you decide that it is just—is an important one.

To produce a good, true wrought-iron which will weld well, and in all particulars take the place of the best puddled iron, use the Bessemer converter or an equivalent vessel, and instead of blowing raw air into it, blow Siemens gas (which contains an excess of carbonic oxide) along with the air, in varying proportions, until at the finish a proper excess of gas is present. To keep the metal fluid with this proper excess, let gas or air, or both, be heated to a sufficiently high temperature before going in, and pass them, in thin streams side by side, under the surface of the metal—that is, through the bottom, sides, or wherever they can be got to go—so that when they come in contact with the metal the mixture may be perfect, and good wrought-iron will be produced. Now, it may be objected that the present action in the converter produces carbonic oxide. True, and I believe that, if it were possible to blow out all the carbon and stop just at the right moment, wrought-iron would be produced; but in reality, the metal would be overblown at one part, while another would contain some carbon, a third carbonic oxide, and so on. If, however, carbonic oxide in excess were blown in with the air, the sum of the actions would, as it were, steady the process all through, and lengthen out the carbonic oxide or wrought-iron period, so that the whole could be brought to the proper quality without fear of being overblown. Again, it may be said that analysis shows that carbonic oxide does exist in overblown Bessemer steel, but always with nitrogen, hydrogen, and oxide of iron, because Mr. Lowthian Bell and Dr. Aldin Wright have shown that carbonic oxide will not take out the last portion of oxygen from the iron oxide (produced by the over-blow), which thus keeps the metal rotten; and besides, the carbonic oxide is not sufficient to do what is expected from it. It is always not any one action which takes place, but the sum or resultant of a great many; and to get the carbonic oxide to do its work properly, it must as much as possible be in excess. The object of this process would be simply to produce wrought-iron, with all its good qualities increased; and although I perhaps ought not to say so here, certain dynamic considerations make it probable that this process would greatly facilitate the elimination of sulphur and phosphorus, while it is but reasonable to expect that its introduction would cheapen wrought-iron as well as improve its quality.

NOTE RELATING TO "WATER-HAMMER" IN STEAM-PIPES.*

By Robert H. Thurston, Stevens Institute, Hoboken, N. J.

The writer has been called upon during the past winter, in the course of his professional work, to examine into the systems of steam heating in use on so large a scale in New York City and elsewhere, and to report upon the condition and capabilities of one of those "plants" which have been put in operation. In the course of this investigation, he was compelled to examine into the peculiar methods of injury to which long lines of steam-pipe thus used are exposed.

The action familiarly known as "water-hammer" had been long known to him, as to every engineer who has had much to do with steam-power, and its singular effects had been often observed and commented upon by him, as by others; but in this case, these effects were developed on so large a scale, and were so serious oftentimes in their consequences, as to impress upon him the desirability of examining into the matter more carefully than had yet been done. He has not been able to make a systematic and thorough investigation such as he would have liked to make; but he has been able to collect some facts, a few of which will be here presented, that may at least have the effect of calling the attention of engineers more generally to this matter, and may lead to further study of the subject.

When a pipe is filled with steam, and then has introduced into it a quantity of cold water, or when a pipe, itself cold, and containing cold water, even in very small quantity, and without pressure, has steam turned into it, the first contact of the two fluids is accompanied by a sudden condensation which causes a sharp blow to be struck, usually at the point of entrance; and sometimes a succession of such blows occurs, which are the heavier as the pipe is larger, and which may be startling, and even very dangerous.

It is not known, so far as the writer is aware, precisely how this action takes place in all cases, or what conditions are most favorable to the development of the tremendous pressures which are often produced. Perhaps the action is as follows:

The steam, at entrance, passes over or comes in contact with the surface of the cold water standing in the pipe. Condensation occurs, at first very slowly, but presently more quickly, and then so rapidly that the surface of contact between the two fluids is broken, and condensation is completed with a suddenness that produces a vacuum. The water surrounding this vacuum is next projected violently from all sides into this vacuous space, and, crossing it, strikes upon the surface surrounding it. As water is nearly incompressible, the blow thus struck is like that of a solid body, and the intensity of the resulting pressure is the greater as the distance through which the portion of surface attacked can yield is less. In this manner, enormous pressures are sometimes produced.

In some cases, it seems certain that such pressures may be caused at points in the pipe far from either end and from the point of entrance of the steam. For example, a pipe may lie in a nearly or quite horizontal line, and, if not fully drained, may contain a considerable quantity of water lying in the lower portion, while the steam may flow in above it. The passage of this steam along the surface of the water may cause some disturbance of the surface of the liquid, and this disturbance being gradually increased as the flow of steam becomes more rapid, may finally cause a break in the surface of the water, which disturbance may produce more rapid condensation and still further agitate the mass, until condensation occurs with such rapidity that a vacuum is formed at the point of greatest action. The next result is the rushing of steam from both directions toward this point, carrying with it, as it goes, masses of water which, coming from opposite directions with enormous velocity, meet at the intermediate spot at which the condensation has been most rapid, and being stopped by instant collision, produce a pressure which may only have as its limit the strength of the pipe.

Where the pipes are not burst by this action, it is common to see them sprung and twisted out of line, torn from their connections, and, when a succession of shocks occurs, as is often the case, the whole line writhes and jumps lengthwise to an extent that is sufficiently serious to cause well-grounded alarm.

The writer had an opportunity, in the course of his work on the case above alluded to, to obtain some probably approximate measures of the intensity of this action in long and heavy lines of pipe. Four lengths of eight-inch pipe had been split by this action, and the writer desired to ascertain whether they remained, in their injured condition, strong enough to bear the ordinary steam pressure of the line from which they were taken. This never rose above fifty or sixty pounds per square inch. They were therefore subjected, in a proving-machine, to gradually increased pressure until the already fractured parts were still further injured, the repairs, or rather, the patching, having been carefully done in such a way that they were not strengthened by it. This was done by putting on soft patches along the line of the split and securing them by bolts which were set in the line of the split. The patches thus served as simple stop-valves, preventing the exit of the water through the break.

The following are the results of the tests:

Pipe No. 1.—This pipe was split, near one end, for a distance of fifteen inches, along the line of the weld. When placed in the proving-machine, it bore the applied pressure until it attained an intensity of 400 pounds per square inch, when the split suddenly extended about ten inches; the pressure could no longer be kept up, and the test terminated.

The pipe was then taken to a pipe-cutting machine and the injured part cut off. It was then again subjected to pressure. It bore a pressure of 1100 pounds per square inch—the highest that it was convenient or customary to apply to that size—and was taken out sound.

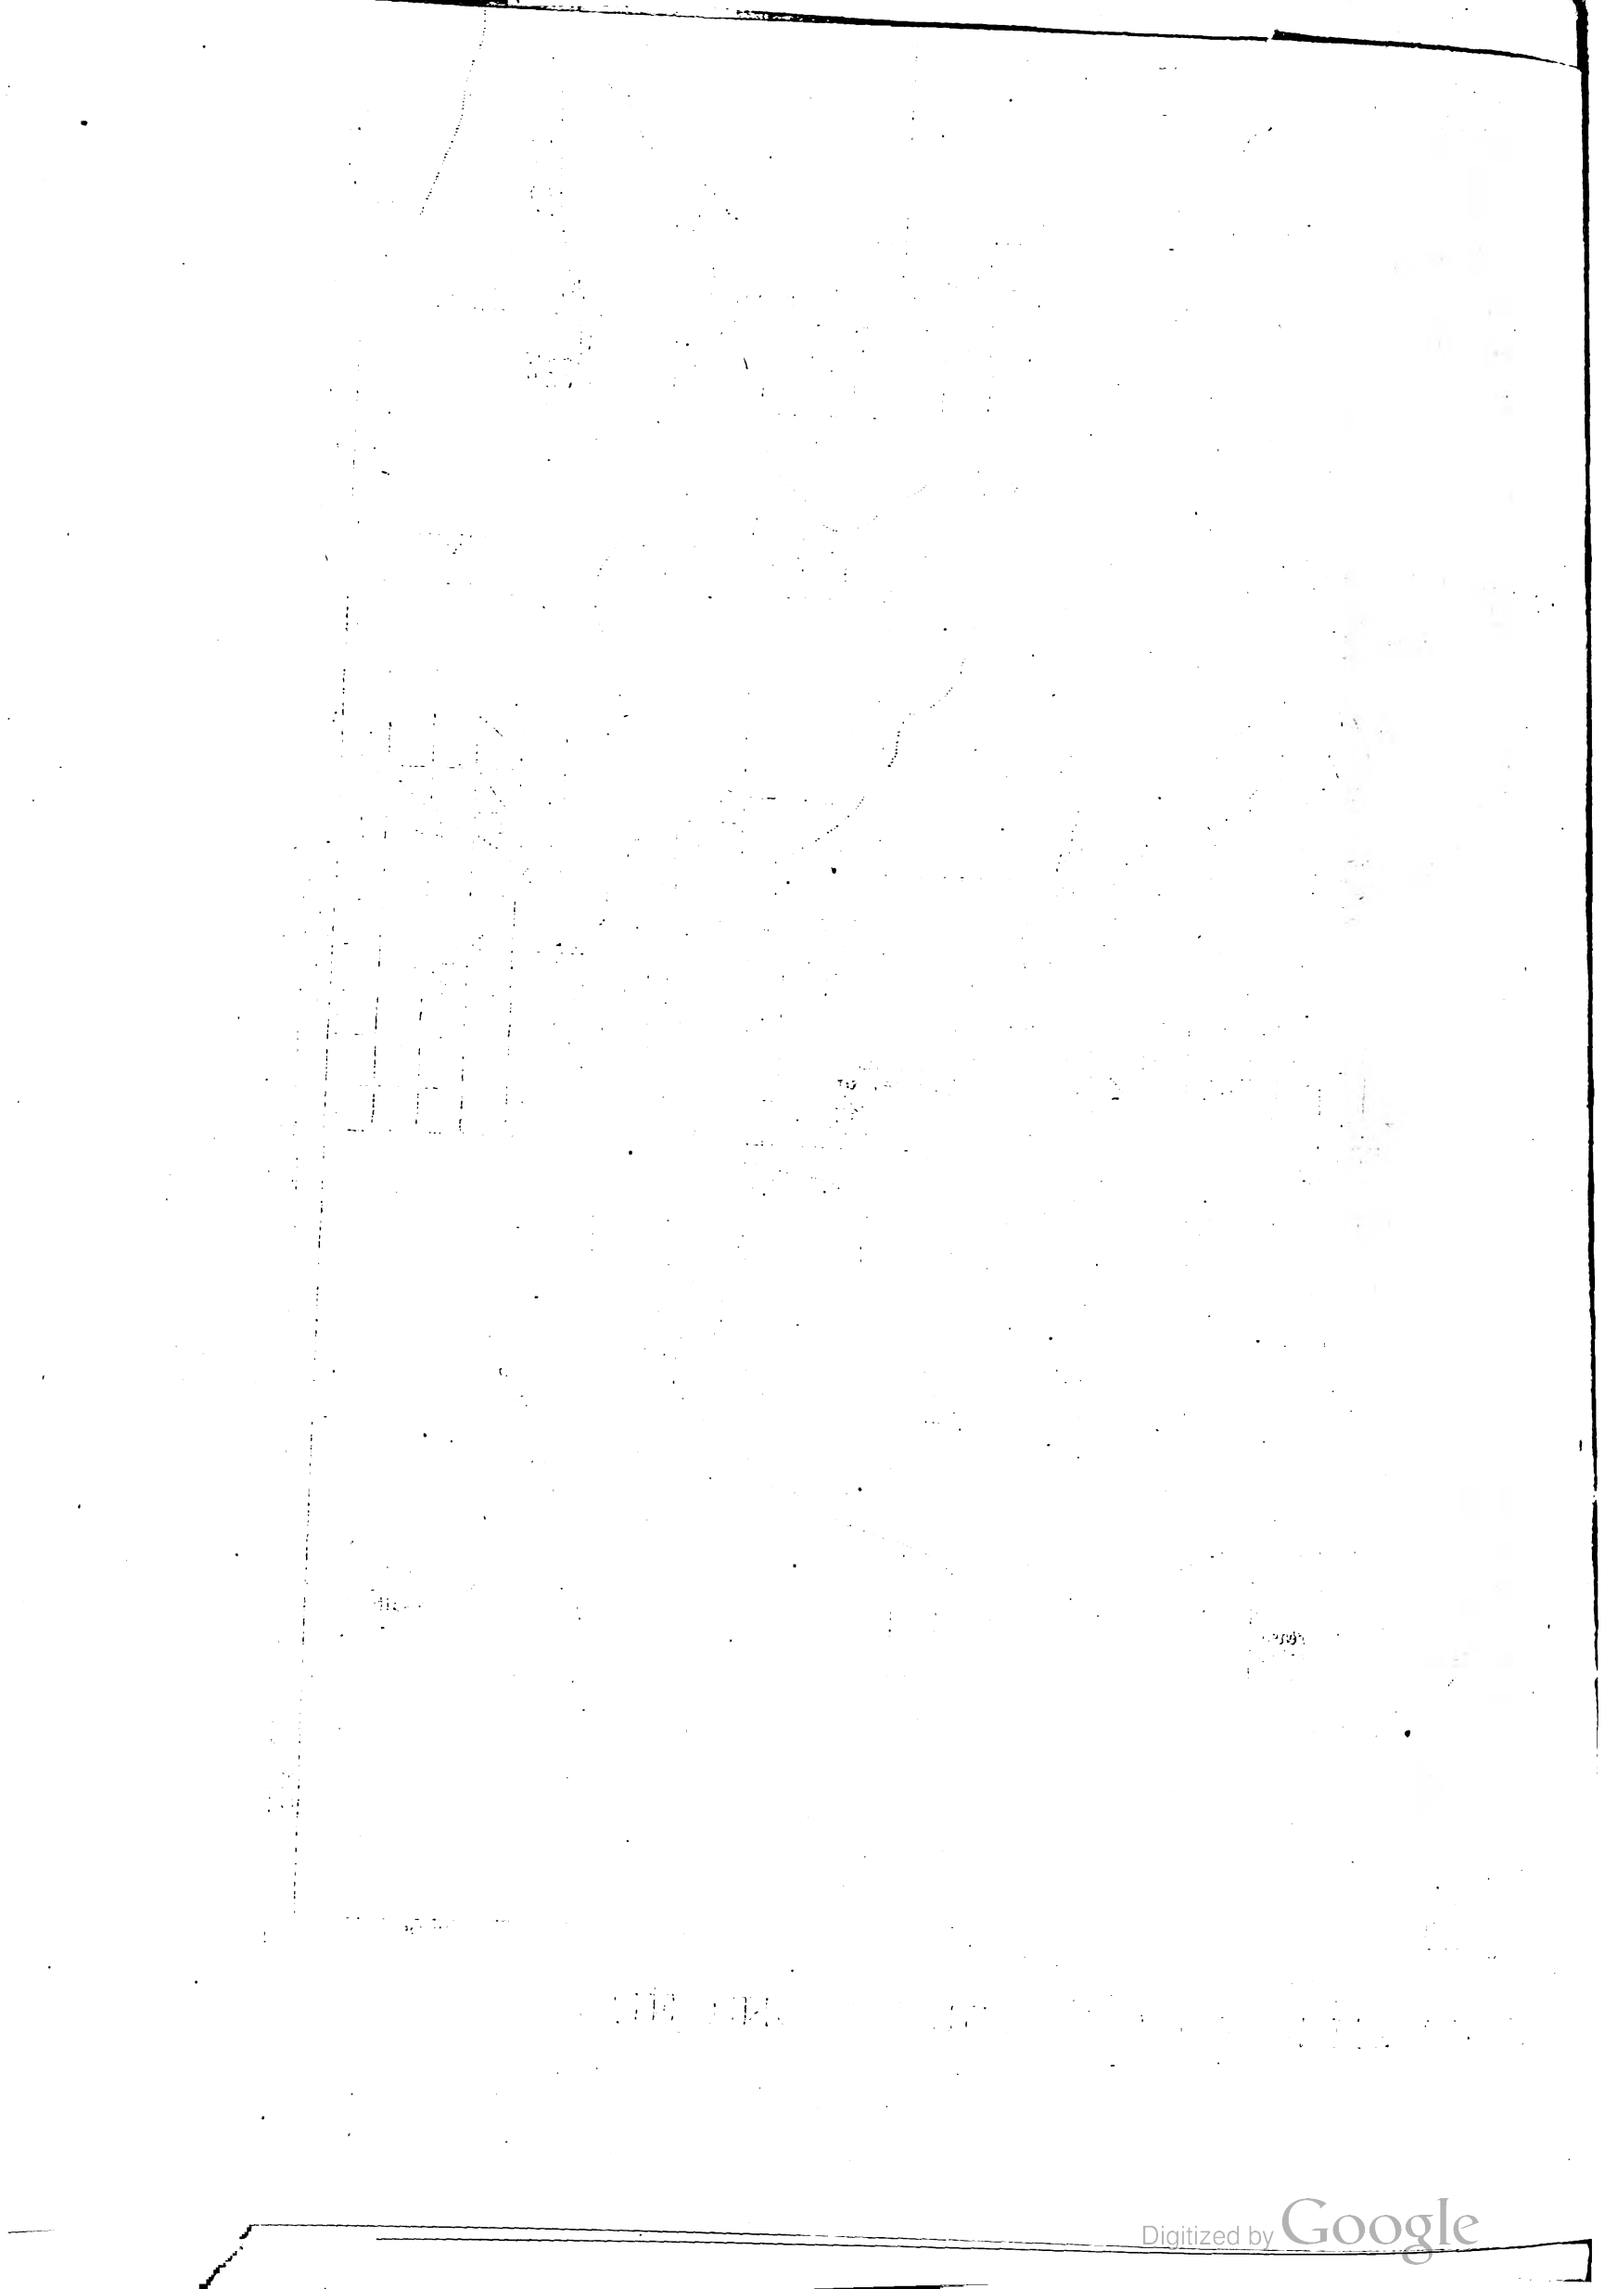
Pipe No. 2.—This length was cracked for a distance of fifteen inches along the line of weld, not far from the middle of its length. The crack had opened a little and the pipe was slightly bulged. This piece bore 800 pounds, and then gave way, the fracture extending just enough to let off the pressure.

At the opposite end of the pipe, was another split, eight inches in length. The part just fractured was cut off, and the remaining portion was again subjected to the water-pressure. This time, it bore 1050 pounds per square inch when the crack was started, and ran about fifteen inches. It began leaking, and showed plainly the effect of the pressure at about 800 pounds.

This was an unusually interesting specimen, as the pipe had been bulged considerably by the water-hammer along the line of the eight-inch crack. The pressure afterward borne, therefore, seemed to the writer to be likely to be a fair measure of that product originally by the water-hammer. Such bulging as was here seen never occurs at usual pressures. The new break did not follow the weld, but ran irregularly, and apparently indifferently, through weld or solid iron.

Pipe No. 3.—This length was split for a distance of 22 inches, the end of the break being about three feet from the end of the pipe. It sustained a pressure of 250 pounds. The sound part of the pipe was then tested up to 1050 pounds without injury.

Pipe No. 4.—This piece was split, like the last, and to just about the same extent, was tested similarly, and gave way at 300 pounds per square inch.



All of this pipe was eight-inch pipe, three eighths of an inch thick, and made with the usual form of lap-welded joint. The welds were not always perfect, as is probably the fact with all such pipe; but this pipe, butt-welded, would have borne very much higher pressures than those to which it was subjected, in ordinary work, by the steam carried on the line. It can not be asserted that these lengths of pipe did not split under pressures less than those to which they were afterward subjected by the writer, as it is very possible that the first blow may have found a weak part of the pipe, and the split may, in some cases, have extended to stronger portions. Nevertheless, the writer is inclined to believe that this was not the case in all instances, and is convinced that, in one case at least—that of the eight-inch crack which was accompanied by a decided bulge in the pipe—the water pressures, at the test, were at least approximately equal to, and are very likely to have exceeded, those obtained at the later test. It seems to him very certain that we may consider it as proved that the pressures produced by "water-hammer" are often enormously in excess of those familiar to us in the use of steam, and that they have, in many cases, exceeded 1000 pounds per square inch. It is, then, evident that it is not often safe to calculate upon meeting these tremendous stresses by weight and thickness of metal, but that the engineer must rely principally, if not solely, upon complete and certain drainage of the pipe at all times as the only means of safely handling steam in long pipes, such, especially, as are now coming into use in the heating of cities by steam led through the streets in underground mains.

The facts here presented have been, to the writer, something of a revelation, and have seemed to him to possess unusual interest and importance to the engineer using steam under such conditions as are here referred to. It is a fact which has long been well known, that these suddenly produced pressures are often very great. The writer has occasionally, for many years, known of serious and sometimes fatal accidents due

to this cause; but that these stresses are often as great as is here indicated, has probably been as little realized by engineers generally as by himself.

DISCUSSION.

CHARLES E. EMERY: The paper of Professor Thurston is valuable, but, I am sorry to say, incomplete. In the first place, the wording of the introduction is unwittingly well calculated to perpetuate a fraud. Last fall, the New York papers were filled with accounts of explosions of steam-pipes, and, in spite of all protests, refused, except in their advertising columns, to call attention to the fact that there were two steam companies, and that the difficulties were on the lines of but one of them. Few read the advertisements, and the press outside of New York copied only the news items, so to this day there is a general impression all over the country that steam enterprise in New York has been a failure. While, ordinarily, engineering facts are valuable, without reference to time, place, or persons, the above statement, with some explanations further on, show the necessity in this case of stating at the outset that the New York Steam Company, of which a gentleman from your beautiful city of Cleveland is president, has not required the services of Professor Thurston, and has been supplying steam continuously since April of last year; while another company, namely, the American Heating and Power Company, the plant of which Professor Thurston reported upon, and ambiguously describes as "one of those plants which have been put in operation," actually ceased operations early last winter, after a few months' abortive trial, and is now in the hands of a receiver, who is endeavoring to sell the property in the interest of the bondholders. The phenomenon of the "water-hammer" is familiar to most steam engineers, particularly those who have had to do with the large pipes used on ocean steamers. The writer, from his connection with the New York Steam Company, had full opportunity to watch the operations of the American Company, and is surprised to find in the paper of Professor Thurston no reference to one of the chief causes of danger in operating the pipes of that company.

Warring nations and political parties have each a war-cry, and an opposition stock company has to have a "tin image on wheels," or a something that can be talked up as being better than the regular thing. Water-gas made a good opposition to coal-gas, and even now is useful in helping the petroleum combinations to work off their naphtha. The people who built the new road through Cleveland, parallel to the Lake Shore, talked "Nickel-Plate"—that is, they did the work well and succeeded in selling out at a profit, as was intended. The American Heating and Power Company did not do this way. They engaged General Newton, who knew how to spend government money, and therefore ought to know about steam, which other people study for a lifetime, and induced him to trail his uniform in the dust of trade. He was their "tin image on wheels," and he invented their war-cry, namely, "superheated steam" (his patent being among the company's effects), and this cry raised the money among brokers, merchants, and clerks who thought they understood all about steam—"superheated steam," at least. The engineer, Mr. R. H. Buel, has done some engineering work of a literary character that is a credit to himself and the country, and should have known better than to attempt to carry superheated steam in underground pipes. One of the consulting engineers, a very able man, should also have known better. Professor Thurston should have known better when he was called in; but the attempt was actually made. The regular superheaters were never used; but a series of pipes in the boiler setting answered the purpose to a limited degree, superheating the steam, it was said, some 60 or 70 degrees, probably more at times, as the demand for steam varied; for who could regulate such an apparatus, or, in fact, any apparatus for such a purpose? The results are evident. Of course, the branches of the line where little or no steam was used soon cooled down, so as to contain only saturated steam, and at times all the branches were in this condition. Upon opening a valve anywhere, however, a circulation would be established, which in due time, but not at once, would bring the superheated steam into that line, and all the conditions of an explosion be present as soon as the steam reached any collection of water, it being evident that water, which is harmless in the presence of saturated steam of the same temperature, would act as an efficient condenser of steam at a higher temperature, though of the same pressure as that due to the temperature of the water. The reduction of volume thus caused would not be as great, of course, as if steam were forced in contact with cold water, but entirely sufficient to cause a flow of steam from both directions, bringing with it more water to reduce the volume of more steam, thereby causing collision; with a necessarily great increase of local pressure, straining the pipes, causing the joints to leak at all sorts of odd places where there were apparently no reasons for the difficulties. The more violent explosions were undoubtedly due to a combination of the straining effects due to the reduction of volume of superheated steam, with the more potent one of direct contact of steam with water cooled below the temperature, due to the pressure during times of inaction, the forces being brought into action more strongly when the steam was conducted through one pipe to heat an adjoining one. The conditions which brought about the bursting of the pipes undoubtedly varied with the circumstances of each particular case and with the peculiarities of each location. As the advance-sheets of Professor Thurston's paper only reached the writer when already busily engaged, a day ahead of the time when this must be sent on to be read in connection therewith, it is not possible at this time to fully discuss the subject, and its consideration in a more serious vein must be left for a proposed paper on the general subject of "District Steam Systems," which it is expected will be prepared when all the problems necessary to a complete mechanical and financial success shall have been analyzed and the necessary apparatus put in practical operation.

PROFESSOR TROWBRIDGE: I am amazed that Professor Thurston should give this paper the distinctive character of personal and individual research on his part. As a matter of fact, the investigations to which he alludes were conducted by a commission, not by himself personally or individually. The American Heating and Power Company of New York requested General Newton and myself to investigate the causes of the bursting of so many of their pipes and the breaking of so many valves in their plant, and I was asked individually to recommend a third member of the commission. I recommended Professor Thurston, and he was appointed. The commission entered upon a long examination, which involved the inspection of the plant, the testing of the pipes which had been burst or split, and the examination of witnesses who were supposed to be expert in steam-fitting. More than two weeks were consumed in these investigations, the results mentioned in Professor Thurston's paper being included in the final report of the commission. That final report was drawn up by myself and, with minor changes, was signed by General Newton, as chairman, Professor Thurston, and myself. The whole subject of water-hammer was discussed for days, and Mr. Frederick Tudor, of New York, at my suggestion, came before the commission, and showed by a simple experiment the effect of condensation to which Professor Thurston refers in his paper. The pipe tests were made by Morris, Tasker & Co. for the commission, and the whole commission was to have been present at the test; but unexpected circumstances prevented General Newton and myself from attending. The results were, however, furnished as a part of the investigation carried out by the commission. In regard to the *theory* given by Professor Thurston of the cause of "water-hammer," whether it be correct or not, it is simply a repetition of suggestions made during those investigations. Mr. Osborne, of St. Paul, and Mr. Frederick Tudor, had each in his extensive practice experienced in a variety of ways the ill-effects of water-hammer, and both confirmed the conclusions to which the commission in its discussions had already arrived. I can not, therefore, let this paper of Professor Thurston's pass without correcting the impressions conveyed by the writer that the results and the report referred to were his own individual productions. Where a commission of experts investigates a subject and makes an official report, as in this instance, it seems to me remarkable that one of the members should allude to its joint investigations and report as his own, without reference in any manner to his associates.

THE TELEPHONE IN A COLLIERY.

A Bell telephone has been fitted up in the Marie pit of the Cockerill Company's colliery at Seraing, Belgium, and has worked without a hitch since the second of April last; so satisfied, indeed, is the company with the experiment, that it is about to put down a telephone in all its shafts. The apparatus on the surface is placed near the winding-shaft, at a point easily accessible to both the day and the night hands. The underground instrument is placed in the main rolley-way, and the wire is protected by gutta-percha, being attached to insulators about every fifty yards. This wire is kept as far as possible from that of the electric signal, so as to avoid any induced currents, which would give rise to difficulty, and even danger; for when the telephone was first put down in the Marie pit, and the call-bell of the telephone was rung, the electric signal was heard at the same time, which misled the banksman. The telephone is found to render great service in the colliery, the ease of communication saving a great deal of time. In the event of an accident to the ropes, the cages leaving the guides, the derangement of the cage signal (whether electric or otherwise), or a stoppage from any cause whatever, instantaneous communication may be made from the bottom to the surface, or *vice versa*.

THE LUMINOSITY OF HEATED GASES.—Dr. Werner Siemens has recently demonstrated, by means of his regenerative furnace, that highly heated gases do not emit light. The furnace employed was that of his brother, the glass manufacturer of Dresden, which gives a temperature of from 1500 degrees to 2000 degrees Centigrade. The interior of the furnace was watched through side-holes, and not the least light met the eye from the highly heated air of the furnace. It therefore appears that all light from heated gas must come, not from the gas, but some solid radiating impurity. Observations with a thermo-pile also seem to show that no heat either is radiated by pure gases at a high temperature.

RUSSIAN BASIC STEEL.—Mr. Sergius Kern, of St. Petersburg, writes as follows to the *Chemical News*: It was a very interesting object for the writer to test the qualities of the basic steel of Russian manufacture. Near St. Petersburg, the Alexandrovsky Steel-Works are commercially working the basic process in Siemens-Martin furnaces.

The plate steel welds quite like iron; in fact, the Nevsky Works, St. Petersburg, rolling the ingots, make, out of the remaining scrap, piles which, heated to a welding heat, are rolled into capital plates for different purposes. The following are the results of trials of the steel plates:

Unannealed Plate.

Thickness in inches.	Breaking weight. Tons per square inch.	Elongation in 8 inches. Per cent.
½	26	29

Annealed Plate.

½	22	36·25

The chemical composition of the steel runs as follows:

	Per cent.		Per cent.
Carbon	0·10	Sulphur	0·02
Manganese	0·43	Silicon	traces
Phosphorus	0·02	Copper	none

I am informed that the raw materials charged into the furnace contain, on the average, 0·75 per cent of phosphorus. I am very happy to state that the great invention of Messrs. Thomas and Gilchrist is worked in Russia in such a satisfactory way.

MESSRS. CRADDOCK & Co., of Wakefield, are now manufacturing a special rope in which the wires and strands are both twisted in the same direction, thus giving a much longer surface of the wire exposed to friction, which lessens, if not entirely removes, the cause of wires breaking on the crown of the strands; and as the working of the rope around drums and pulleys bends the wires in an oblique direction, the greatest amount of wear possible from the wires is secured, as they will not break until too much reduced, and become therefore too weak for their work. The wires in the strands on this principle have a longer bearing one against another than in the ordinary system, and

Digitized by Google

prevent much injury which results from the wires in each adjoining strand cutting into one another. There are claimed for this rope greater durability and immunity from wires breaking when but slightly worn, which has caused many ropes to be put aside as useless. One of this make, 4½ inches circumference, and 350 yards long, was used at Blackwell, from July 31st, 1880, to September 23d, 1882. When taken off, there were only six or eight broken wires in the entire length; but as the wear on each outside wire was so nearly the same, thus making possible the collapse of a good number at once, it was thought advisable to put on a new one.

FURNACE, MILL, AND FACTORY.

The fillers at A. M. Byers & Co.'s Girard furnace have struck against a reduction of fifteen cents a day.

A test was made recently, in Philadelphia, of a cold-packed pipe-joint, as operated by the Consolidated Pipe-Joint Company; and though a pressure of 240 pounds to the square inch was applied to the pipes, not a drop of water escaped from the joint. The test was made at the machine-shop of John Baizley & Son, No. 513 Penn street, in the presence of a number of visitors. Among those present were Gas Trustees Smith, Kelly, Gill, and Rittenhouse; President Smith, of Select Council; Superintendent de Kinder, of the Water Department; and ex-Governor Hoyt. The packing is of lead, which is cast in a belt about the pipe close to the joint, and too large to fit the opening which it is intended to calk. After the lead is cooled, hydraulic pressure is applied to the belt, and it is forced into the pipe-socket, making a perfectly tight joint. By the present method, molten lead is run into the joint. On cooling, the lead shrinks, and it is necessary to use oakum calking to make the joints tight. The economy claimed for the new method is, that it saves 60 per cent in lead, makes a joint that will not leak, saves time in operating, and can be used in a smaller trench than is required for the present system of calking.

The Northwestern Steel Wheel Company has recently been incorporated, and is at once to erect works at Chicago, Ill. Its purpose is to manufacture a newly patented steel wheel for agricultural machinery. Its works will consist of a machine shop and foundry.

The *Industrial World* says that the Fowler Rolling-Mill Company, Chicago, has recently doubled its capacity for the manufacture of the Fowler spike by the placing of an additional train of rolls, a 100 horse-power engine and boiler, and additional furnaces. By some improvements lately made by Mr. Fowler, he is enabled to carry an old rail from the furnace and convert it into finished spikes in fourteen seconds. By this process, the usual reheating of the iron is obviated. The company has just purchased the remainder of the block adjoining its works, which will give it the necessary enlargement of the plant.

The Fort Pitt Steam Boiler and Plate Iron-Works, of Pittsburg, Pa., formerly operated by D. W. C. Carroll & Co., are now wholly in the hands of Mr. D. W. C. Carroll, who was the senior member of the old company.

Park Brothers & Co., of the Black Diamond Steel-Works, Pittsburg, have closed a contract with John Roach & Sons to furnish a large amount of steel to be used in building the government vessels.

Greenwood rolling-mill, Tamaqua, Pa., which was closed some time ago by the failure of C. F. Shoener and the Greenwood Rolling-Mill Company, has been leased by Messrs. Daniel Snepp and H. A. Weldy, who will start the mill some time this month. They will engage principally in the manufacture of hoop and merchant iron.

The largest weekly production of iron made by a furnace in Sharpsville was that produced by Spearman No. 2 last week, the output being 728 tons, or 104 tons per day.

By act of legislature, the name of the Orford Nickel and Copper Company has been changed to the Orford Copper and Sulphur Company, proprietors of the Bergenport Copper-Works. This change has been made as indicating more clearly the business carried on by the company, it having discontinued the mining and smelting of nickel ores. The company purchases, and refines and sells on commission, copper ores, cements, mattes, and bullion. Mr. Robert M. Thompson, Nos. 37 and 39 Wall street, being general manager; W. E. C. Eustis, of Boston, president; and C. F. Atkinson, of 19 Exchange place, Boston, treasurer.

The Murphy Iron-Works, of Detroit, have just set up two of Murphy's smokeless furnaces for J. S. Kirk & Co., Chicago, and are now busily constructing six more, for which orders have been received.

The Chicago Gas Fuel and Light Company is laying three principal mains in Chicago and erecting its works preparatory to prosecuting its business with vigor. The works, covering an area of 265 by 374 feet, are located at the corner of Hanover and Butler streets. The company will use the Lowe water-gas process. It will start with a daily capacity of 3,000,000 feet, and possesses sufficient room to enable it to double that capacity, if required. The machinery is now getting into place, and the company will be ready for business November 1st. Four purifying-boxes, 25 by 30 feet, with 30-inch seals, and two holders with capacity of 1,250,000 feet, will be used. By November 1st, 100 miles of pipe will be laid, including a 24-inch main surrounding the south side of the city. In these preparations, 800 men are employed, and 900 consumers have contracted to take gas from the company.

The American Forsyth Powder Company, of California, has purchased five hundred acres of land near Shippenport, Morris County, N. J., for a consideration of about $11,000. The land is in one entire tract, unbroken by a county road. The works, when completed, will cost nearly $1,000,000. The property is the tract at Shippenport which was owned by the Dover Bank, but does not include the forge. The bargain for the property was consummated about two weeks ago, and the papers sent West for the signature of Mr. James B. Lewis, one of the officers of the late bank, who is now making a visit to Dakota.

Four hundred men are thrown out of work by a fire which destroyed the shops of the New Haven Rolling-Mill Company, on the 15th. The loss to the company in buildings and machinery is about $50,000. The fire broke out over the annealing-boxes. It could have easily been put out when discovered, but no water was to be obtained. The city water company had cut off the water supply to the mill, in order to make repairs to the mains.

A terrible boiler explosion occurred at the anthracite iron furnace of the Philadelphia & Reading Railroad, at Kutztown, on the morning of the 17th. At four o'clock, the inhabitants of the place were aroused from their slumbers by a rumbling sound like that of an earthquake. This was followed a second later by a shock that was strong enough to knock people from their feet. It was found that one of eight boilers walled in had exploded. The furnace is operated by Messrs. William M. Kaufman & Co., and the casting hour was half-past four A.M. Just before the final preparations were made, the men went outside to get some fresh air. Suddenly a terrible noise of escaping steam was heard, and the next instant the boilers were lifted with a crash and the furnace was a wreck. Large portions of the boilers were thrown long distances, and the air was filled with flying *débris*, among which were the mangled and lifeless remains of the workman. One large piece of boiler iron was sent flying through the air, and landed nearly a quarter of a mile from the boiler-house. The stock-house of the furnace, the boiler-house, and adjoining buildings were torn to splinters. Four men were fatally injured, and many others sustained serious injuries. The only man killed was Franklin Waltman, twenty-one years of age. He was fearfully lacerated, and his body, limbs and head were a charred mass. The damage to the property will amount to many thousands of dollars. The seven boilers that were thrown out of position by the explosion were badly damaged. The furnace will have to be entirely rebuilt.

The steel-mill and two of the furnaces of the Bethlehem Iron Company were put in operation on the 19th, and the force of men will be increased daily until the full number is at work. About 100 men have been sworn in to do special police duty and to protect the workmen should an attack be made upon them by the Union men.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY.

CONTENTION.—The work of enlarging the main shaft to admit pump-works is pushed vigorously. The uprise from the bottom of the shaft has reached a distance of 255 feet. From the surface, the compartment is down 30 feet. The pumps have arrived, and the work of building the stone foundation will be commenced in a few days. Prospect-work in the mine has been discontinued during the enlargement of the shaft. Enough ore is, however, daily extracted to keep the mill running.

GRAND CENTRAL.—No important developments are reported. Work is progressing as usual.

TOMBSTONE MILL AND MINING COMPANY.—A new concentrating mill is building at Charleston, with a capacity of 100 tons per day, to be used in concentrating tailings. Fifty tons per day are forwarded to mill and smelter, supplied mainly by West Side, although Tough Nut and Good Enough are yielding considerable amounts.

GILA COUNTY.

OLD DOMINION.—According to the Globe *Chronicle*, this company has bought all the property and plant of the Long Island Company, consisting of the Cuperite, Gray, Hoosier, and Nevada mines, and the thirty-ton smelter. It is probable that the furnace will be moved to the site occupied by the other Old Dominion furnaces, and that all four stacks will shortly be running steadily. It is stated that the company also proposes to smelt copper ores for mine-owners in the district, and that probably an additional furnace will be erected for that purpose.

YAVAPAI COUNTY.

RICH HILL GOLD MINING COMPANY.—The prospectus states that the property of the company consists of a gold-bearing ledge 1500 feet long by 600 feet wide, situate in Weaver Mining District, Yavapai County. The ledge or claim is named the Van Arman claim, and was located in 1882. Some work was done on the ledge—sufficient to demonstrate its richness. The ledge is seven feet wide, a true fissure-vein. Assays from croppings show all along the ledge that the quartz is rich in gold. The nature of the country is rough, although there is plenty of wood near the mine. Water is, however, scarce, and in milling will have to be carried one mile in pipes, unless a well is sunk or water is found in the mine.

CANADA.

PROVINCE OF ONTARIO.

ROBERTSVILLE.—The iron mine, on account of depression in the iron trade, has been obliged to close down. The Roberts Company mined about 100 tons per day and employed about twenty men, whose wages averaged $4000 per month. The Levant mine is still in active operation.

COLORADO.

ARAPAHOE COUNTY.

Smith, Hibbard & Co. are just completing a new crusher and smelter in Denver, which is expected to do work cheaper and better than any now in use. Though some parts of the machinery are still unfinished, enough has been completed to enable the management to run fifteen or sixteen tons of very refractory ore per day of twelve hours. Just at present, experiments are making with some heavy zinc ore with a view to save the zinc. Should these be successful, a new industry would at once be instituted in Colorado; for while there is an abundance of ore carrying 50 per cent of zinc, no process has heretofore been able to separate it. This ore is known as sulphate of zinc.

BOULDER COUNTY.

MATTIE.—This mine has been bought by the same company which purchased the Keystone some time ago. Machinery will be placed on the workings at once, the same now used on the Keystone. The latter property will be supplied with a new plant of machinery, which has been purchased and will arrive immediately. It is rumored that a smelter will be erected in connection with the concentrator.

CLEAR CREEK COUNTY.

HOOSAC.—At the Little Mattie mine, the property of this company, the shaft has attained a depth of 280 feet. The 150-foot level is in over 200 feet west of the shaft, and the lower or 250-foot level has been run 150 feet west. Three shifts are driving the latter ahead, on a good ore-streak, while for a year past stoping has been carried on in the upper level. The ore mills high in silver and gold, averaging about $200 per ton. The monthly shipments are from twenty to thirty tons. The new engine-room, shaft-house, and ore-house have just been finished. The new machinery, consisting of a thirty horse-power hoisting-engine, and two thirty horse-power boilers, is in place and works satisfactorily.

PERKINS TUNNEL LODE.—This mine, at which a recent rich gold strike was made, is rapidly developing. Several new shafts have been sunk in tracing the vein. Several tons of ore will be sent to the mill in a few days.

SUMMIT TUNNEL AND MINING COMPANY.—The tunnel has been driven steadily ahead into Belleview Mountain, until now they have reached a depth of tunnel near 600 feet. At the expiration of their present contract, steam-drills, air-compressors, and all the necessary machinery for driving the tunnel 3000 feet will be put in place. This company owns nine patented lodes in this mountain, all of which will be cut by its tunnel, which is driven 5½ by 7½ feet in size. Up to this time, nothing but solid granite has been met with. The company expects to strike its first lode at about 1000 feet, and will eventually reach the Specie Payment lode, which will be struck at great depth. The enormous outlay necessary for the completion of this tunnel, and before any returns for the capital invested, shows the confidence the incorporators have in this district, and their enterprise.

DOLORES COUNTY.

SOUTH PARK.—Since the change in the ownership of this mine, it has been worked steadily. The tunnel is in 300 feet from its mouth, and a cross-cut has been run 35 feet to the south, where the flat or blanket vein was struck. A rise has been made 15 feet high, and in ore all the way. A drift has been driven 40 feet farther south, in the vein. This drift is 4½ feet wide and 6½ feet high, all in ore. The ore of this mine is in black manganese, carrying sulphurets and large quantities of native silver. The ore mill-runs from 175 to 450 ounces of

Digitized by Google

silver per ton, and from 10 to 15 per cent of lead. The mine is shipping from 10 to 12 tons per day.

GILPIN COUNTY.

It is stated that a party of capitalists will erect a stamp-mill in or near the mouth of Moon Gulch, which will be run on custom ore from several of the developed mines in Boulder District. There is plenty of wood and water near at hand. It is expected that the mill will be up and running in ninety days.

CALIFORNIA.—No work is done below the 1300-foot station in the main shaft, now 1450 feet deep. Since breaking the steel wire cable, sinking has ceased, the water now being nearly up to the 1400-foot station. A new cable is expected, when the water will be taken out and the sinking resumed.

HIDDEN TREASURE.—The main shaft has attained the depth of 1400 feet, making it the deepest mine in the State of Colorado. Present development-work is doing in the 1500-foot west level. The 1400 level, when driven to the California mine on the east, will strike that shaft at the depth of 1500 feet, there being a difference in the elevation of the ground of 100 feet.

GUNNISON COUNTY.

The Gunnison Iron and Steel-Works have, after a thorough examination of the properties on Gold Hill, purchased the claims known as the Deadlock, Bullion King, York, Sinbad, Michigan, and Iron Mountain. These claims all lie to the south of the wonderful Cumberland, whose production of iron is well known. The vein that crops boldly to the surface on the Cumberland is easily traced to the apex of Gold Hill, across the above-mentioned claims, which, only partially developed, show that the iron exists in large bodies. Work has already been commenced, and the force will be increased to 200 men very shortly.

HINSDALE COUNTY.

MASTODON.—The run of this ore at the Crookes concentrator has been a success. Out of the nine tons run through, there are three tons of concentrates, two and a half of which will give 70 per cent lead. The other half is second-grade, with more or less lead. The ore was not assorted, but taken from the width of the vein.

LAKE COUNTY.

Late Leadville exchanges contain the following: "It has long been realized," says the *Herald-Democrat*, "that the facilities for treating the ores produced in this district were entirely inadequate, and, as a result of this, a new smelter is about to be provided under a co-operative system. Several meetings have been held in reference to the scheme, and the conferences have been most satisfactory. At least one million dollars will back the enterprise, and it is expected that work will begin very shortly."

ADAMS.—This company has been organized to work the Brookland and Clontarf mines. The pumps at both shafts are running at full capacity, and the Clontarf shaft, already free from water, will begin taking out ore immediately. As soon as the transfer of the properties is completed, an effort will be made to connect the two shafts by a level, when the Brookland will be used principally for pumping, while the extraction of ore will be carried on through the Clontarf.

EVENING STAR.—The recent new strike shows a gray sand and hard gray lead carbonate, assaying respectively five ounces in silver and fifty-eight per cent in lead, and eleven ounces in silver and thirty-three per cent in lead. The new discovery is considered of importance, as up to the present time the mine has failed to disclose any ore in this portion of the claim, although several winzes were sunk to the ore-plane as the incline advanced.

GLASS-PENDERY.—The property has opened a large body of iron ore, through which are disseminated good-sized pockets of fine ore. Shipments of iron ore, running from six to eighteen ounces, are made regularly, while at short intervals lots of very fair ore are sent to the smelters. The mass of iron developed in the mine is very large, and being situated below the old working-levels in the mine, it was considered advisable to drive a drift to connect the ore-body with the Glass shaft. Only about twenty feet yet remain to be cut through, when the connection will be effected, and the ore can then be extracted at greatly reduced expense.

LITTLE PITTSBURG *vs.* LITTLE CHIEF.—Col. J. B. Bissell, referee in the case of the Little Pittsburg *vs.* the Little Chief Mining Company, July 13th, returned a verdict awarding the Little Pittsburg Consolidated Mining Company $19,400 and ten per cent interest per annum for nearly three years. The history of the case is about as follows: During October of 1880, while Mr. John T. Herrick was manager of the Little Chief mine, he learned of a fair streak of ore situated on the line of the Little Pittsburg claim, which his predecessor, Mr. George Daly, had left standing and lagged up. Mr. Herrick directed his foreman to take down the lagging and extract the ore. On these orders, the miners of the Little Chief entered the premises of the Pittsburg and began the extraction of ore, following the ore-body for about thirty feet. Hearing work in progress, the Little Pittsburg immediately drove a drift to intercept the trespassers, but failed to reach them until, it is alleged, about thirty thousand dollars' worth of ore was broken down and shipped by the Little Chief Company. Evidence for a suit for damages was immediately collected, and a suit instituted. Numerous delays followed, and finally Col. J. B. Bissell was appointed to receive testimony, and listen to the arguments of the attorneys. In justification of his act, the manager of the Little Chief alleged that, while connected with the Little Pittsburg mine, that company obtained twice as much ore from within the boundaries of the Little Chief claim, and now connecting with the Little Chief, and seeing an opportunity to equalize matters, he embraced it, and stoped the ore from the Little Pittsburg territory as alleged. The Little Chief filed a claim as an offset to that of the Little Pittsburg, and of nearly double the amount, and also attempted to show that the claim of the Little Pittsburg was excessive.

MATCHLESS.—A ten-ton lot of ore, averaging 375 ounces to the ton, was shipped recently. The northern workings of the mine now show about six feet of lead carbonate ore, the greatest quantity of this character ever disclosed in the Matchless. The southern portion of the claim is disclosing additional pockets of rich horn-silver.

NEW PITTSBURG.—Considerable work is in progress on the property of this company.

ROBERT E. LEE.—A great deal of exploration-work is doing at present.

ST. LOUIS.—This mine on Breece Hill, is making some very fair ore-shipments. The property embraces the principal portions of the former Colorado Prince and Miner Boy mines, together with the main shafts, tunnels, and buildings on these properties. During the past few weeks, the lessees have shipped about fifty tons of low-grade oxidized ore, the value of which has not yet been ascertained. The mine also produced, and in various small lots, some quite high-grade gold ore.

PARK COUNTY.

LONDON.—A special dispatch says that this company's stamp-mill has been demonstrated a success. The clean-up amounts to from 155 to 150 ounces of amalgam in twenty-four hours, worth from $800 to $1000. It is believed the mill will produce $1000 a day from London ores steadily and without increasing the capacity. Embrey concentrators are to be put in the mill to work over the concentrates.

PITKIN COUNTY.

ST. ELMO CONSOLIDATION.—The mines embraced in this property are located in Conundrum Gulch, a short distance from Aspen, and during the present season have been worked with considerable activity. A shaft seventy-five feet in depth has been sunk at the St. Elmo mine and has been drifted from in all directions. The shaft has penetrated a good body of quartz carrying silver glance, and assays have been had as high as five thousand ounces. In the development of the claim, about one hundred tons of ore have accumulated upon the dump, and it is the intention of the owners to begin the shipment of this matter to the Aspen smelter at once.

SUMMIT COUNTY.

CINCINNATI.—This mine has been leased. The lessee has done a considerable amount of development-work, cleaning out old tunnels and shafts. This property was once thought to be the most valuable in Summit County, but for several years has been suffered to lie idle. General Wilson, the lessee, has a contract to operate the mine for several months, and expects to ship three car-loads of galena per week.

KEYSTONE BULLION COMPANY.—The works are running to their full capacity and are concentrating nearly 100 tons daily, which will give about two car-loads of concentrates per day. The principal source of supply is from Mayo Gulch, the Washington group, the Penn-Breckenridge property, and the Union mine, also the IXL property at Swan.

DAKOTA.

CALEDONIA.—The superintendent reports for the week ended July 1st: Ore produced, 1050 tons. We have not started the drifts in the winze, but have begun stoping ore there. Every thing in and about the mine is running in good shape. July 8th, reports: Ore produced, 1025 tons. Shipped 59$\frac{5}{8}$ ounces gold, value $10,000. The ore on 400-foot level at bottom of winze is looking well as work advances. The mill is running to its full capacity.

FATHER DE SMET.—The superintendent's report for the week ended July 8th, shows ore extracted from first, second, and third levels, 1950 tons. Ore milled, 1950 tons. Golden Gate north header advanced 7 feet. Header in 165 feet.

IDAHO.

High water in Snake River has somewhat interfered with mining. The sluice-boxes have generally been temporarily removed, but are replaced as the water subsides. Two new companies are just beginning work. One company is making a ditch on the west side of the river. It is stated that the St. Paul Placer Mining Company is going to do work on a large scale.

PHILADELPHIA MINING AND SMELTING COMPANY.—Good progress is made at the company's works. The mines are opening up well, and showing large quantities of ore that can be extracted at slight cost as compared with most of the mines in this section. The two old smelting-furnaces of the company are doing good work and running right along, turning out from one and a half to two car-loads of base bullion per day. The two new furnaces just erected are ready to start. When the four furnaces get to work, they will reduce about 120 tons of ore, and yield from 40 to 50 tons of bullion per day. The works, started as an experiment, are now an assured success. They have, during the past two months, received ores from over fifty mines. The quantity of ore so far received exceeds 2500 tons, of which nearly a thousand tons remain in the bins at the works. This ore came from mines scattered all over the Wood River or smelting section, and averaged 55 per cent in lead and about 100 ounces in silver.

MEXICO.

A correspondent of the Mexican *Financier* writes about the mines at Tlalpajahua as follows: Tlalpajahua is in the northeast corner of the rich State of Michoacan, close to the boundary of the State of Mexico, and within about four miles of Mineral del Oro in the latter State. At Mineral del Oro, an American company is putting in a twelve-inch pipe pump, and fine hoisting machinery, and is building reduction-works. Not less than 3000 miners can be had here at 50 cents a day, and common peons at 31 cents. There is plenty of low-priced fuel; oak-wood at $4 a cord, and pine at $3. The streams here have plenty of water in the rainy season, and from February to June they become low; but at any time, there are not less than 100 miner's inches of water, and it would be very easy to use it as a motive power and for hydraulic purposes. What we greatly need here are reduction-works with two or three stamp-mills of from 50 to 100 tons capacity each. There are here fourteen quartz-veins varying from six inches to 15 feet in width, and there are over one million tons of rejected ores on the old dumps giving from $10 to $25 a ton. Our city is paved with quartz, and there is no doubt that some day some smart American company will undertake to mill all this quartz and to pave over the streets of Tlalpajahua with the regular country-rock. The arrastra men are hauling ore from the old Corona's and Borda's dumps as far as sixteen miles, working the ores on the ancient and primitive arrastra, saving some of the gold, the rest being lost, together with all the silver.

Tlalpajahua is about nine miles south of the Mexican National Railroad, and is convenient to two stations, El Oro and Tepetongo, to which we have very good wagon-roads. There are ten or fifteen mill-sites here, with more or less water-power. Some new locations have been made here lately, among them one by several employés of the Mexican National Railroad. They have almost one kilometer in length on the Temascales vein, one of the good veins of the camp. They are working steadily, and before long will cut the main vein. Not less than fifty smaller mines are idle for want of reduction-works, as all we have here now is a five-stamp mill, made by Fraser & Chalmers, of Chicago, which is worked by water-power with fine results. This mill is working the ore of the Concepcion group of mines, the owners of which are both Mexicans and Americans. They have ore as rich as $500 to the ton, but never less than $50. The ores of the different veins of the camp are almost all of the same kind—quartz with sulphurets and native silver; some chlorides may very rarely be seen, but all the ores have high grades of gold.

Several of the mines are capable of producing from fifty to several hundred tons of ore daily; among them may be counted the Coloradillas, Santa Rosa, Azteca, San Juan, Concepcion, Borda, La Nacional, Jesus María, and fifty more. Several other mines can produce very rich gold ore, and their output is from five to twenty-five tons each, daily. Among them are the Sirena, Comanja, El Muerto, La Trinidad, Santa Rita, La Casa, and many more smaller veins. In fact, what we need here is modern-process milling-works, capable of reducing from 50 to 100 tons a day; and before a year or two are passed, this camp can produce ten times that amount, as here are hundreds of mines now just on the surface with none of them more than two or three hundred feet deep, with the exception of the Borda, which is about 400 feet deep. These Borda mines produced over $35,000,000 just before the war of independence, but they are now full of water. The Borda group is owned by a Chicago company, which has been fixing the roads from the town to the mines, and extensive machinery is expected to be working there before long.

The mining interests at Zomelchuacan, Vera Cruz, continue to be most encouraging. A new gold mine has recently been denounced in the district.

Some very good lead mines have lately been opened near Jalacingo. The ore assays 70 per cent lead and eight ounces of silver to the ton of 2000 pounds.

CONSOLIDATED MINING COMPANY.—This company of Zomelchuacan has sent its first bar of gold to the mint. More will be sent as soon as it can get the new amalgamating pan which has been ordered. The company has been building quite extensively for the new smelter, which will probably be soon in operation

Digitized by Google

There is a considerable quantity of lead carbonate ores on hand to start it up with.

MIQUITA.—A rich vein of ore carrying gold has been recently struck.

SAN JUAN DE DIOS.—This mine, situated in the Hermosillo District, Sonora, has been sold to an American company for $87,000.

MICHIGAN.

The Marquette *Mining Journal* gives the following table, which exhibits in gross tons the total lake shipments of iron ore from upper peninsula ports the present season, up to and including July 11th, together with the amount shipped from the same ports during the corresponding period of last year :

Name of port.	1882.	1883.
Escanaba	726,403	480,869
Marquette	406,980	183,821
L'Anse	17,338	18,377
St. Ignace	10,427	2,518
Total	1,161,148	685,585

Showing a decrease of 475,563 gross tons.

CHAPIN.—At the west end of the mine, the ore-body shows a width of from 100 to 130 feet of ore ; and as the Ludington has 103 feet of ore on the same vein at the most easterly point to which mining work has reached, it is quite apparent that the Chapin has a body of ore yet untouched within the limits described. An attempt to reach this ore by a shaft put down in the overlying quicksand has been made, but was not successful, and the management will adopt some other plan of attacking it.

FRANKLIN.—In the interest of economy, the management is preparing to use coal on the mine for steam purposes. A tramway from the lake front to connect with the foot of the incline is just completed, which will be used in transporting coal to the top of the hill with but one handling.

OSCEOLA.—Preparations are making to erect another head of Ball's stamps in the dressing-works.

ROPES GOLD MINE.—The boiler for this mine is now in place, and, as soon as the steam-pipes are in, the pumps will be started up and the shaft unwatered, when mining will begin in earnest. Sinking and drifting will be prosecuted, and the lode shown up as fully as can be. The mill is ready to begin stamping as soon as the power to drive it is in shape.

MISSOURI.

THE NEW ST. JOSEPH CONCENTRATING MILL.—The St. Louis *Republican* has a letter from a correspondent in which he gives the following details on the new St. Joseph concentrating mill, at Bonne Terre, built to replace the works destroyed by fire on February 25th :

The rebuilding of these works was begun on the ninth day of March last, and on the 25th of June instant, one of the largest and most complete mills in existence, occupying the sites where the old mill stood, and filled with improved machinery for dressing ores, was completed and set in operation.

The main building is 150 feet long by 122 feet wide. The engine and boiler-houses at the north end of the mill are respectively eighty feet long by thirty wide and ninety by forty. The boiler-house at the south end (partially completed) is sixty feet long by forty wide, and the machine-shop is fifty feet long by twenty-five wide. Except the lower story of the main building, all these structures are built entirely of iron on stone foundations. The lower story is built of oak timber, but covered with corrugated iron. It has three hundred and fourteen upright columns, sixteen inches square, which carry the crushers, rolls, screens, pipes, and pumps, all below the main floor, and support the long lines of shafting. There are in this mill six Blake crushers, seven pairs of Cornish rolls, sixteen double percussion-tables, thirty-six double horizontal jigs, thirty-six plunger jigs, two Wilbraham pumps, with a capacity of 3500 gallons per minute ; five Knowles pumps ; fifteen centrifugal pumps ; thirty-three mortised, beveled, and spur-gear wheels ; 120 pulleys, and over 3000 feet of belting. This machinery is operated by two Harris-Corliss condensing engines, having a combined capacity of 300 horse-power, built in Providence, R I. Five batteries of boilers supply the engines with steam. Three months and a half from the day on which the first stone was laid in the foundations of these buildings they were virtually finished, and the entire machinery, made in many different places throughout the country, was in place. The engines were started and tested on the first day of June, instant, and now hundreds of wheels are making their rapid revolutions and answering the purposes for which they were devised.

MONTANA.

GALLATIN COUNTY.

HENRY VILLARD HYDRAULIC GOLD MINING COMPANY.—A description of this company's property shows the following : The mines are situated in Emigrant Gulch, about twenty-five miles from Livingstone, on the road to the National Park. The company owns what is believed to be the old channel of the gulch. It has about 380 acres of ground. A small portion of this has been worked continuously for the past twenty years, and has yielded a large quantity of gold. One claim now worked by hand yields a net profit of $11 per day to each man. Since purchasing the ground, the company has sunk five prospect-shafts twenty-five feet deep, and they show good pay-dirt all the way down. This, however, does not take them down to bed-rock, there being from sixty to one hundred feet of gravel on the bed-rock as shown by the old workings. The company owns the Mill Creek water-right ; and for the purpose of more extensive operations than at present, it proposes to construct a ditch eight miles in length, to bring its waters to the mines. It will have a capacity of six thousand inches, which will be fully sufficient for all requirements. Thirty new claims adjoining this ground have been taken up recently, for the working of which water will be procured of the company.

MADISON COUNTY.

BELL.—This mine, situated in the vicinity of Virginia City, is developed by two tunnels, one of which is over 400 feet. The average width of the vein is 15 feet, and the rock assays 40 ounces of silver, with considerable gold.

PROSPECT.—This property has a shaft 35 feet deep, from the bottom of which is a level 220 feet, the ore along the ledge assaying 50 ounces in silver. Still below is a tunnel in 200 feet, the ore assaying about the same as in the upper level ; and still below this is another tunnel, in 400 feet, which assays 40 ounces. The width of the vein where it has been struck in all the tunnels and levels is from ten to twelve feet. One hundred and sixty feet from the mouth of the lower level, starts an incline, which is down 35 feet.

VIRGINIA CONCENTRATING COMPANY.—A concentrator of 130 tons capacity is building at Virginia City for the purpose of testing the ores in the immediate neighborhood. It it should prove a success, more extensive works will be built.

SILVER BOW COUNTY.

ALICE.—A three-foot ledge of 277-ounce ore has been uncovered on the west drift from the 200, which is undoubtedly the same vein which has been stripped on the 100-foot for a distance east and west of over 300 feet. Cross-cutting to intercept this body of ore will be commenced immediately from the 400-foot level.

BELL.—The concentrator has started up, and it is expected will work from 60 to 70 tons of ore from the low-grade dump per day.

NEVADA.

ALBION.—Since so many varying reports concerning this property have been published recently, the Eureka *Sentinel* has felt obliged to give the correct facts. They are stated as follows : At the time the last assessment was levied, Selby & Co., smelting and lead company, the principal creditors of the Albion Company, agreed to advance sufficient funds to pay off the miners and laborers, who held liens against the mine to the amount of $45,000, which they did advance in cash. They were also willing to postpone the payment of their own claim, amounting to $120,000, as well as that of Prescott, Scott & Co., foundrymen, amounting to $20,000 more, in order to give the mine a chance to work itself out of its financial embarrassment by allowing it to run and to be developed. It was then considered by the trustees of the Albion that, if an assessment of 50 cents per share, amounting to $75,000, could be collected, it would put the mine in such a financial condition as to relieve it of its pressing necessities, and enable it to carry on the work of development. It was with this view that the 50-cent assessment was levied. The stockholders, however, refused to pay the assessment, which brought into the treasury of the company 112,000 shares of the delinquent stock. But neither the trustees of the Albion nor the creditors are responsible for that. It is true that the mine has been advertised for sale for a claim of $1800 by a party holding an execution ; but this claim was settled on the 1st of July, and the execution withdrawn. There is no expectation here that the mine will be sold at all ; but we have it from the best authority that it will not only not be sold, but that it is the intention of the present management to push the development of the mine with the utmost vigor, and that it is not an exaggeration to assert that the Albion mine will probably be entirely out of debt within the course of the present year. It may be safely predicted also, that within a few months the condition of the mine itself will be better than ever before. A later report by the same paper states that 25 tons of ore were hauled from the Albion to the Eureka Consolidated furnaces, July 9th, the first shipment since the recent adjustment of affairs and the general transfer of accounts to Prentiss Selby.

EUREKA CONSOLIDATED.—An official letter shows that at the Locan shaft the main drift is running as rapidly as possible. One furnace is running and producing as usual. The following prospect-work has been done during the week : 3d level uprise on quartzite, 12 feet ; in all, 64 feet. Main drift, Locan shaft, driven this week 42 feet ; in all, 47 feet.

UTAH.—The following gentlemen were elected to serve for the ensuing year at the annual meeting : Charles H. Fish, President ; R. H. Follis, Vice-President ; G. C. Pratt, Secretary. The Board of Trustees is as follows : Charles H. Fish, Richard H. Follis, and D. B. Lyman. The superintendent's report shows that a great deal of repair work has been necessary to keep the openings in a safe condition. At the 1350 level, the south lateral drift has been cleaned out and retimbered 775 feet to the company's south line. At this point, the drift connects with an incline winze leading up to and connecting with the Sierra Nevada 1200-level drift, which runs in a southerly course to that company's shaft. Through these openings, we get natural ventilating air. The drifts also contain the pipes which convey the water from the mine to the Sutro Tunnel. At a point 315 feet north of the incline, No. 1 crosscut has been extended 87 feet ; total length, 207 feet. This drift has been advanced farther to the west than any other without finding the west wall. At the 2500 level, the east main drift has been extended 69 feet, the face of which is in very hard rock and free from water. No work has been done in the south lateral drift during the year. The flow of water remains unchanged. An unlooked for expense has been incurred in repairing drifts and water-pipes through which the water flows to Sutro Tunnel. Early in March last, the pipe burst at a point 1100 feet south of the Sierra Nevada shaft on the 1500 level. Owing to foul air and the caved condition of the drift, it was impossible to reach the break until ventilating-pipes had been put in, and the drift cleaned out and repaired for a distance of 600 feet. When the break had been reached and temporarily repaired, I deemed it an economical measure to abandon cleaning out and retimbering the remaining 800 feet of drift to the point where the pipe connects with the Union shaft drain-pipe. Instead I am now running a drift from the Union shaft drain tunnel, 1600 level, having first made an uprise of 25 feet. This drift is now extended from the top of the uprise 180 feet, leaving 60 feet to run to connect with 1500 level Sierra Nevada drift at the point where the pipe was repaired. This work will be completed and pipes laid through the new drift by the end of the present month. The machinery is all in good working order. The pumps are running successfully, and the water is down to the lowest point in sump.

UTAH.

FRISCO.—Large quantities of ore are produced daily. The company has 3000 feet of tunnels, shafts, and rises. The vein will average thirty inches all through the mine. The lower tunnel, to tap the vein at a depth of 200 feet deeper than the present vein workings, is in 240 feet, and according to the survey there are only thirty-six feet more to run to strike the vein.

SILVER MOUNTAIN.—The report presented at the annual meeting, held at Salt Lake City recently, shows that the tunnel has a total length of 386 feet. At this point, a fine body of carbonate and galena ore was encountered, varying in width from one to five feet. Assays made show 43 per cent lead and 82½ ounces of silver per ton. The composition of this ore is such as to render it an exceedingly fine ore for smelting. Extracting and shipping ore will begin as soon as the developments in the level run from the point where the strike was made are sufficiently advanced.

The purchase of the Dexter mining claim, adjoining the Silver Mountain, for $2000 in money and 500 shares of stock, is also reported. The width of the vein not being determined, and the ore-body being unexplored, I considered it of great importance to secure the adjoining ground before the extent of the strike becomes known, and therefore advised the purchase, which secures the company a large and very valuable tract of additional ground.

TINTIC DISTRICT.

The mining outlook in this district is good, with the exception of the Mammoth property, which is lying idle, not from any fault of the mine, but from bad management. The Eureka mine is turning out about thirty tons of ore per day, which is shipped to Colorado to be smelted. The Beck mine is working about twenty men, and the property is looking fair, and the output is regular. Messrs. Smith & Martin have taken charge of the Red Bird Consolidated at Eureka, and are putting in fine steam hoisting-works, among the best yet erected in the district. The Park property has a concentrator at work. The gangue or waste from this mine is very soft, and easily washes away, leaving the concentrates in the form of lead ore very rich in silver. The Old Chicago has a good strike on it, lately made in the well-defined ledge, which runs about 100 ounces in silver. The Northern Spy is supplying the Tintic mill with ore, and is doing a good business, and has a steady output.

VERMONT.

VERMONT COPPER MINING COMPANY.—The company has now paid one third of the amount due for laborers' wages for the months of May and June. The company as at present organized will not resume work, and the mines will probably be idle the rest of the year or longer.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, July 20.

The mining market has been very dull this week, and the transactions afford little or nothing of interest to note. Eastern Oregon and Sonora have been the most active stocks dealt in, while Horn-Silver has displayed the most strength. Below will be found a complete summary of the market. The total number of sales aggregates 115,559 shares, as against 224,910 last week.

The Comstock shares have been very quiet at weakening prices. Consolidated Virginia, with a fair business, was irregular, selling from 40 @32@35c.; Sierra Nevada sold at $3.90, with a small business. Union Consolidated has been quiet and weak, selling from $5.50@$4.75. Mexican sold at $2.85. Consolidated Imperial records small sales at 4c. Sutro Tunnel has been moderately dealt in at steady prices; it sold at 19@20c.

The Leadville stocks were but moderately dealt in, and were steady. Amie sold from 14@12c., under small transactions. Chrysolite was quiet and steady, selling from $1.15@$1.10. Dunkin sold at 20c. Iron Silver records a fair business at strong prices, selling from $2.95@$3.10@$3. Leadville sold at 50c. Little Chief, with a small business, was irregular, selling from 50 @51c. Little Pittsburg was quiet and a little weak, selling from 70@65c. Climax sold from 13@10c., with small transactions.

The Bodie stocks were very quiet and weak. Bodie Consolidated was weak, a sale of 100 shares being quoted at 69c. Standard had a small business at weak prices, selling from $7@$6.50@$6.63. North Standard sold to-day at 7@8c.

The Tuscarora stocks record small transactions at steady prices. Grand Prize sold at 31c., and Argenta at 35c. Belle Isle was moderately dealt in, and was weak, selling from 45@39c. Navajo records a small business at steady prices; it sold from $2.85@$3. Elko Consolidated was quiet and steady at 22@25c.

In the miscellaneous list, Alice has been quiet and weak at $2.70@$2.50. Caribou records a small business at steady prices, selling from 12@13c. Green Mountain was quiet and irregular, selling at 71@73@72c. Homestake shows some strength under small transactions; it sold from $16@$17. Horn-Silver has been fairly dealt in, and has been quite strong; it sold from $6.88@$8@$7.75. Northern Belle was quiet and steady at $6.25. Robinson Consolidated has been very quiet at steady prices, selling from 61@60c. Sierra Grande was moderately dealt in and was weak; it sold from $1.25@$1. Stormont sold from 48@37c., with a small business.

Alta-Montana was quiet at 2c. Bradshaw records a fair business at weakening prices; it sold from 28@25c. Caledonia was quiet and steady at $1.15. Decatur sold from 3@5@4c., with small transactions. Eastern Oregon was actively dealt in at strong prices; it sold from 72@76c. Oriental & Miller was quiet and steady at 14@13c. Sonora Consolidated was very active at irregular prices; it sold from 29@25c.

A suit has been brought to dissolve the American Mining Stock Exchange, and for the distribution of the insurance and gratuity fund to its members. The Exchange gave up its rooms at 63 Broadway last May, and since that time its members have disbanded and joined other exchanges. Action is now brought for the purpose of having a receiver appointed to take possession of the fund, which amounts to about $10,000.

The Governing Committee of the New York Mining Stock and National Petroleum Exchange has reduced the fee for transferring seats in the Exchange from $100 to $25.

DIVIDENDS.

The Father de Smet Consolidated Mining Company, of Dakota, has declared its twenty-eighth dividend of twenty cents per share, payable July 31st.

PIPE LINE CERTIFICATES.

As will be seen by our table below, this week has been a very active one in the oil market. A decline set in in the early part of the week, and was only checked to-day, when strong figures prevailed. There was no news of importance from the oil regions to affect the market.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
July 14.....	$1.08	$1.08¼	$1.03⅞	$1.04⅝	3,646,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, July 19.

The market has lapsed into a state of extreme dullness again, the transactions being almost entirely confined to the stock of one mine on the list, namely, Quincy, which declined from $50@$48, with some pressure to sell the stock. Only one share of Calumet & Hecla changed hands, and that at $239, ex dividend $5, an advance of $1 over last sale. A small lot of Osceola sold at $21, and this comprises all the transactions in the copper-mining shares for the week. The brokers in these specialties certainly have reason to complain of the stupidity of the market, and are anxiously looking for a better time coming.

In silver stocks, with the exception of Silver Islet, there is not much change. The report from Silver Islet of a rich strike in the 1160 level has brought some buying orders, and the stock advanced from $4@$7½, with sales of about 600 shares. Sullivan declined from $1¼@75c., and at the Mining Board, sales were made at 62½c., seller 60 days. Catalpa and Cresent, both dull on the poor showing for June; the former declined from 57½@45c., the latter sold at 25c. Bonanza declined from $2¼@$2.

At the Boston Mining Exchange, there is less activity than last week, and prices are a shade lower. Bowman Silver declined from 27@21c., and Massachusetts & New Mexico got back to its old price again, 7c., sales. There was considerable doing in railroad stocks, Toledo, Cincinnati & St. Louis being most prominent, with sales of over 1000 shares at $3⅞@$2⅞, the latter figure being to-day's price.

3 P.M.—At the afternoon Boards, there was little doing. We note sales of Bonanza at $2. Quincy, at $48. Huron, at $1½. Silver Islet was offered at $7; no bid. Catalpa, 47½c. bid. San Pedro, 27½c. bid. $240 was bid for Calumet & Hecla. Franklin offered at $10. Pewabic, $3½ bid; and Atlantic, $11 bid.

BULLION MARKET.

NEW YORK, Friday Evening, July 20.

As foreshadowed in our postings of the 13th inst., our silver market has declined, and is weak at the figures of annexed table.

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.
July 14	50⅜	110⅛	July 18	50 5-16	110
16	50⅜	110⅛	19	50 5-16	110
17	50⅜	110⅛	20	50 5-16	110⅛

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14½ per cent, to arrive at actual value.

MINES.	States.	Month of June.	Year from Jan. 1st, 1883.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended July 20th, as compiled from various sources, amounted to $131,262, as against $176,000 reported for the previous week. The receipts from January 1st, 1883, to date are $6,295,474.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended July 14th	$278,469
Corresponding week last year	225,000
Since January 1st, 1883	7,069,935
Corresponding period last year	36,372,334

Imports.

Week ended July 14th	$158,780
Corresponding week last year	16,609
Since January 1st, 1883	7,136,602
Corresponding period last year	2,021,989

Foreign Bank Statements.—The governors of the Bank of England, at their weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 4 per cent. During the week, the bank lost £87,000 bullion, and the proportion of its reserve to its liabilities was reduced from 42 5-16 to 41 7-16 per cent, against 40 3-16 per cent at this date last year. June 19th, the bank gained £17,000 bullion on balance. The weekly statement of the Bank of France shows losses of 1,450,000 francs gold, and 2,275,000 francs silver.

METALS.

NEW YORK, Friday Evening, July 20.

Copper.—We confirm the favorable indications of last week, though it can not be said that as yet they have had any effect upon values. There is less pressure to sell than there has been for a long time, and inquiries for Lake from people who have not been supplied under the pool sales are getting more numerous. Odd lots are picked up for export at 15@15⅛c., which is the ruling quotation, while other brands are 14@14⅛c. The English market has retained its steadiness, although some of the merchants' circulars are bearish in tone, probably in opposition to the parties who are apparently getting ready for a squeeze, should business revive in the fall. London cables £63 10s. for Chili Bars.

To-day, the members of the Exchange took a turn at copper, and sales of 50,000 pounds of Lake at 15c. and 100,000 pounds at 15⅛c., and 150,000 pounds of Baltimore at 14⅛c. and 50,000 pounds at 14c. were recorded.

Tin.—Outside of the Exchange, where 350 tons of tin were sold, the business of the week has been quiet. The spot is concentrated in a few hands, and we quote spot Straits, round lots, 21¼@21⅜c. London cables £93.

Lead.—In the beginning of the week, 400 tons of Newark sold at 4·30c., and 400 tons of St. Joe lead at 4·32½c., and since then there have been small sales at 4·35c., for Common, which we quote. The large holders, among them the Richmond, hold firmly, and have not been sellers, and while there is no active demand, the offerings, too, are small. Refined may be nominally quoted 4·35@4·40c., nothing being done.

The telegraphers' strike has prevented the receipt of our usual dispatches from St. Louis and Chicago. England cables £12 10s. for Spanish.

Spelter.—This metal appears unable to rally, and we note sales at 4⅜c., a figure at which even some of our Eastern works must find it hard to compete, while Europe is out of the race entirely. England cables £15 5s. for Silesia.

Antimony.—There is nothing special to note. Quotations are 9¼@9⅝c. for Hallett's, and 10¼@10⅝c. for Cookson's, advices from England being lower.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, July 20.

Telegraphic dispatches are at hand, announcing the failure of the Manchester Iron and Steel Company, at Pittsburg.

American Pig.—The firmness which we have so frequently dwelt upon, so far as prime brands of No. 1 is concerned, continues, while No. 2 and Gray Forge are quiet and easy. Furnace agents report a fair business, the Thomas Iron Company alone having contracted for 3000 tons at full figures.

At the Metal Exchange the following sales have been reported during the week:

Monday, 100 tons No. 1, October delivery, at $22.50, and 200 tons at $22.37½. Tuesday, 500 tons at $22.25, 200 tons at $22.37½, 400 tons at $22.12½, and 1200 tons at $22, all October delivery, and 100 tons at $22, 200 tons at $21.87½, and 200 at $21.75, all September delivery. On Thursday, 200 tons October were sold at $22.12½, and to-day 300 tons, November delivery, from $22.50 down to $22.25. We quote at tide-water, spot, according to brand, $21.75@$23 for good to choice No. 1, $19@$20 for No. 2, and $18.50@$19.50 for Gray Forge. Nothing has been done in Bessemer pig. England cables 50@51s. Spiegeleisen is quiet, with 20 per cent quoted $30.50@$31.

Scotch Pig.—There has been an advance in freights, which are now quoted by cable 9@10s. from Glasgow to this city, which induces importers to assume a firmer attitude, though business is not large and arrivals continue light. We quote ex ship: Coltness, $23.75@$24; Langloan, $23.75@$24; Summerlee, $23@$23.50; Dalmellington, $21@$21.50; and Eglinton, $21.

At the Exchange, the following cable quotations were received: Coltness, 61s. 3d.; Langloan; 60s.; Summerlee, 57s. 6d.; Gartsherrie, 57s. 6d.; Glengarnock, at Ardrossan, 55s.; and Eglinton, at Ardrossan, 49s. 6d. Warrants to-day were 47s. 4d.

Rails.—We hear of sales aggregating 15,000 tons, partly for early delivery, at $38½ at mill. There is considerable inquiry for small lots for such delivery, which has reacted somewhat favorably upon sales for fall and early winter. England is unchanged.

Old Rails.—There are several good-sized lots in market without eliciting bids higher than $21@$22.

Scrap.—Old material of this description is dull and lifeless at $22@$22.50 ex ship.

Philadelphia. July 19.

Eastern Pennsylvania iron quotations stand as recorded last week, and transactions up to present writing, for this week, show firmness in all except inferior makes of crude iron. Consumers are ordering quite freely, for near-by use, but can not be induced to place orders for remote delivery, as they look for a further weakness before the opening of the regular fall trade. Several furnaces are preparing to go into blast, and, should there be any material increase in the output, the present upward tendency will be arrested and uncertainties and fluctuations gather around the trade. The present output is apparently sufficient to meet actual requirements, and firm prices can be held. Special No. 1 Foundry sold to-day at $23.50, and all furnaces are well sold up for the summer output. The standard brands are held with considerable firmness, although occasional transactions have leaked out at lower than quoted rates. Very little good No. 1 has been sold below $22, and some firms hold at $22@$22.50. No. 1 iron, no better than No. 2, is sold at $21.50. No. 2 averages $20. A number of transactions for ordinary makes were closed at $19.50. The mill-owners are preparing to resume, and some few orders for 500-ton lots have been placed at from $17.50@$18 at furnace; $17 iron is to be had, but there is less of it offering than two or three weeks ago.

There is some little inquiry for Scotch iron, but very little is doing. Bessemer iron is dull, and quoted nominally at $21.50, but large consumers will not pay that price. A good deal of ore is arriving.

Spiegeleisen is quoted, $31 for 20 per cent; with buyers waiting, at $30.

Sales of Muck Bars have taken place between $34 and $35, with a tendency toward the lower figure. Best Charcoal Blooms command $61, and small sales have been heard of from this down to $56, and from $47 to $50 for different makes of anthracite.

Merchant Bars are held at 2·20c., but the business done below this is increasing. In view of the increased output, buyers are more exacting, and it is harder to place orders at 2·20c. Small lots are 2·25c. Stores are doing a fair business. Country mills are selling their inferior makes all the way from 1·90@2·10c.

Nails.—Inquiries for nails begin to improve, and prices remain substantially as heretofore quoted, $3 to $3.15. The Western suspension will help demand here. Fall requirements will be heavy. Offers of less than $3 have not been accepted.

In structural iron, plate and tank, and all kinds of sheet-iron, a fair movement is reported, though very little has been done in the way of anticipating September requirements.

Steel rails are quoted $38@$39, and thus far it appears that makers have the advantage in negotiations. Offers of $36@$37 have terminated in orders at $37.50 and $38. Western mills are taking large orders at $39@$40. The demand for railroad material is satisfactory, and prices are strong.

Pittsburg. July 19.

The improvement in the iron market which was noted last week continues, with the result of drawing out a good deal of inquiry during the past few days, and a moderate number of orders for immediate delivery.

The fact is more clearly brought out that supplies in consumers' hands are lower than prudence permits, and some of the larger consumers have placed orders for two or three weeks' requirements, intending to await further developments. The holders of the Marshall iron have quieted the market by the assurance that they will not unload it in bulk, but will dispose of it in a manner that will not unduly influence the market.

The nail men have shut down for a month, in order to keep prices where they have been for ninety days. Stocks are low in first and second hands, and they will be able to maintain prices where they are by the present policy. Steel mills are partially idle for repairs. The supply of all kinds of steel is heavy, and prices weak. Inquiry for old rails is active and negotiations for large lots are pending. Bessemer iron is quoted at $21.50. No. 1 Foundry, $19@$21. Old Rails, $22.50. Red Short mill iron, $18.50. Warm-Blast Charcoal, $26. Cold-Blast, $28@$30. Muck Bars, $34.50. Demand light. Merchant Bar, 2c. in small lots and 1·90c. shaded in large lots. Nails, $2.90. Wrought Pipes, $70 and $80. Track supplies are in active demand and unchanged. Crop-Ends, $25. Scrap Iron is in fair demand at $22 for Common, and $23@$24 for Selected.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, July 20.

Anthracite.

As anticipated, the month continues to be a very dull one. There is considerable coal moving, to fill June orders, but new business is very small in volume and is generally made on the basis of June prices, lower figures being more frequent than higher ones, practically no coal selling at circular rates, except the best Lehigh coals.

News from the West, which is now the principal point of interest, is not particularly encouraging, though no signs of any sharp competition appear on the surface. The Executive Committee of the Western Association met last week at Buffalo, to straighten out some of the irregularities in that market.

President Roberts, of the Pennsylvania Railroad, called a conference at Philadelphia, on Friday last, of the Western shippers of anthracite coal over his road. The probable effect upon the Westward coal tonnage of the Pennsylvania Railroad of the completion of new connections of coal roads to the West was fully discussed, and it is stated that the railroad officials showed their determination not to permit any diversion of trade, but to do all in their power to keep it in its present channel.

It is not believed that the heavily increased tonnage can be placed on the Western markets without some struggle, and it is feared that, if prices should suffer too much there, while well maintained here, the diversion to the seaboard might demoralize the trade

John H. Jones, official accountant, has just published the following statement of the anthracite coal tonnage for June, 1883. The figures include the entire production of anthracite coal, excepting that

* Included in tonnage of Philadelphia & Reading Railroad.

† This amount includes the production of the mines of the State Line & Sullivan Railroad Company, amounting to 5718 tons.

‡ In addition, there were 47,377 tons transported from mines by Delaware & Hudson Canal Company, during June, which is included in tonnage of other interests.

The stock of coal on hand at tide-water shipping points, June 30th, 1883, was 592,309 tons ; on May 31st, 1883, 645,377 tons ; decrease, 53,068 tons.

Bituminous.

There is absolutely nothing to report in the bituminous market, which remains stagnant with low prices induced by the sharp competition among producers, the rivalry of the two leading regions, and the efforts of new classes of coal to gain a foothold in the market. Quotations remain nominally unchanged.

STATISTICS OF COAL PRODUCTION.

Comparative statement of the production of anthracite coal for the week ended July 14th, and year from January 1st :

Horsford's Acid Phosphate
For Women and Children.

Dr. Joseph Holt, of New Orleans, La., says : "I have frequently found it of excellent service in cases of debility, loss of appetite, and in convalescence from exhaustive illness, and particularly of service in treatment of women and children."

DIVIDENDS.

OFFICE OF QUINCY MINING COMPANY.

NEW YORK, July 11, 1883.

DIVIDEND NO. 30.

THREE DOLLARS AND FIFTY CENTS ($3.50) per share will be payable August 15th next, to holders of record 24th inst. Massachusetts holders will be paid at the office of Mr. N. H. Daniels, 2 Change Avenue, Boston. By order of WILLIAM ROGERS TODD, Treasurer.

SAN FRANCISCO, July 13, 1883.

THE FATHER DE SMET CONSOLIDATED GOLD MINING COMPANY has declared

DIVIDEND NO. 28,

of TWENTY CENTS per share, payable at the office of Laidlaw & Co., No. 14 Wall Street, on the 31st inst.

Transfer-books will close on the 23d inst.

H. DEAS, Secretary.

STEAM PUMPS.

FOR SALE.—A large number of Steam-Pumps of all makes, and ranging in size from small tank or boiler feeds up to very heavy service machines.

While the stock lasts, good bargains are open for Miners, Water-Works, Rolling-Mills, Furnaces, or any one needing to move fluids by steam. Call upon or address

JOHN A. HINCKLEY, Purchasing Agent of
THE UNITED PIPE LINES, OIL CITY, PA.

SMELTING-WORKS FOR SALE.

The New England Smelting-Works, on Chelsea Street, East Boston, are now offered for sale.

There are two buildings, each 50 feet square, a large refinery, nearly the same size, and an office ; two copper and two lead furnaces; an engine, a crusher, lead kettles, cupel furnace, and all necessary tools and appliances, platform scales, etc., for carrying on the smelting business.

The land is 200 feet front, running back over 800 feet to tide-water.

Price low, and terms to suit the purchaser. Must be sold. Apply to

A. R. BROWN, Jr.,
38 Water Street, Room 1,
BOSTON, MASS.

THE Moore method of blasting with lime cartridges has been tried in one of the collieries of Messrs. BERWIND, WHITE & Co., in the Clearfield region, without success, the coal, it is said, being too soft.

THE Charcoal Iron-Workers are going to invade Michigan, beginning on the 14th of August with a visit to Detroit, its copper-works, and the Eureka and Hamatramck iron-works. Reaching St. Ignace on the 16th, they propose to visit the Martel furnace, and, on their way to Marquette, the Vulcan furnace. Just how they are going to divide themselves up to see all that is to be seen in the Marquette iron region, is not yet decided ; but as the association has already acquired fame as being intensely eager for business, we have no doubt that it will accomplish a good deal in the brief time allotted to it.

To all those who have watched with interest the first experiment with the Wallace Arbitration Act in the Pittsburg rail coal trade, the tidings that have come from there will cause lively satisfaction. It will be remembered that some weeks ago, Mr. MCCUNE, the arbitrator, made an award, fixing the price for mining per bushel of coal at 3½ cents. Operators and miners in a large number of pits promptly acquiesced in this decision, and for a short time every thing looked bright. Unfortunately, there were a number of pits in which the miners had agreed to work for three cents irrespective of what the award might be, and their adherence to this agreement threatened to make the arbitrator's decision a dead letter. The curious spectacle was presented of the majority of operators and miners in the district earnestly co-operating to bring about one end, the cessation of work on a three-cent basis in the off pits. For more than a week, they labored in vain ; and the first attempt at settlement by arbitration threatened to be a failure, until, a few days ago, success crowned their efforts, and now almost every pit along the Pan-Handle road is working at the compromise rate. The temper shown by both parties is, to say the least, an encouraging sign for the future. The hardships of both men and operators are undoubtedly great. With nut coal selling on the wall at Pittsburg for 5¼@5¾ cents per bushel, little local demand for slack, and fierce competition in the lake trade, the profits of the shippers must be small indeed, if there is not in many instances a positive loss. The outcome of the Pittsburg experiment will give encouragement to the moderate element in other districts. Thus, we note with pleasure that the Iowa miners and operators, at a meeting at Des Moines on Wednesday, chose committees to arbitrate on the screen question, which has been a very troublesome factor for years.

THE PIG-IRON TRADE.

The American Iron and Steel Association has accomplished a feat of which the officers of that organization and the members of the iron trade may well be proud. The *Bulletin* this week contains full statistics of the production of pig-iron during the first six months of the year, and the stocks on hand and unsold. To gather such figures for an industry so widely scattered over so great a territory, and publish them complete three weeks after the close of the period for which they were collected, is a remarkable proof of excellence of organization and industry. It reflects great credit, too, upon the trade itself, showing how intelligently such work is appreciated.

An analysis of the figures, a summary of which we can only print, will, we believe, show in a general way that the pig-iron trade has reached a sound basis. The production of all kinds of pig-iron was as follows, for the first six months :

PRODUCTION OF ALL KINDS OF PIG-IRON.

STATES.	In blast Jan. 1st.	In blast June 1st.	FURNACES JULY 1ST. In.	Out.	Total.	TONS OF 2240 LBS. One half of 1882.	First six mos. 1883.

Tennessee	14	11	8	11	19	61,429	64,872
Ohio	62	41	44	49	93	312,009	319,238
Indiana	2	1	....	3	3	4,464	4,850
Illinois	9	7	7	9	16	160,896	108,832
Michigan	14	11	12	17	29	93,837	72,518
Wisconsin	8	6	5	10	15	38,330	26,041
Missouri	3	6	5	12	17	50,734	41,200
Minnesota	1	1	....	1	1	3,028	3,035
Utah	....	....	....	1	1	26	.....
Colorado	1	1	1	....	1	10,588	11,325
Oregon	1	1	1	....	1	3,013	5,800
California	....	1	1	....	1	441	900
Washington Territory	....	1	1	....	1	.....	2,800
Total	417	351	334	354	688	2,311,062	2,352,019

Turning first to the figures for the production, it will be seen that the output has been heavier thus far than it was last year, when the total production marked the unprecedented total of 4,623,333 gross tons ; but this excess, 40,357 tons, is so light, and the number of furnaces blown out recently is so great, that the total for this year will beyond all doubt be below last year's figure. The falling off is heaviest in the West and less striking in New York and New Jersey, while Pennsylvania shows a heavy increase, half of which is due to Alleghany County. The Southern States show an increase of about 30,000 tons, an evidence of the recent activity in that section.

Grouped according to the fuel used, the figures stand as follows :

PRODUCTION ACCORDING TO FUEL USED.

KIND OF FUEL.	In blast January 1st.	In blast June 1st.	FURNACES JULY 1ST. In.	Out.	Total.	TONS OF 2240 LBS. One half of 1882.	First six mos. 1883
Anthracite	161	137	125	96	221	911,669	906,870
Charcoal	129	105	98	149	247	311,505	250,719
Bituminous	127	109	111	109	220	1,088,428	1,194,430
Total	417	351	334	354	688	2,311,062	2,352,019

This proves that as yet the blowing out of furnaces has not made a very

Digitized by Google

strong impression upon the quantity of metal made. It is well known how difficult it is, from the nature and costliness of the operation, for a furnace-man to make up his mind to stop being a producer, and the pig-iron trade is therefore always the slowest to recover. That buyers need not fear an early scarcity of metal is clearly shown by the following statement of stocks:

STOCKS ACCORDING TO FUEL USED.

	On hand Dec. 31, '82.	On hand June 3, '83.
Bituminous	140,353	196,099
Anthracite	95,767	186,735
Charcoal	147,535	145,756
Total	383,655	528,590

The heaviest increase in pig, smelted with bituminous coal and with anthracite, is in Pennsylvania, while the exceptionally heavy stocks of charcoal pig are concentrated in the South, and particularly in the West and Northwest.

The data for the number of furnaces in blast are of interest so far as they go. They would, of course, be much more valuable if a reliable estimate of their capacity were added. The *Iron Age* attempts to gather such figures; but the large number of differences between their figures for the number of furnaces in blast and those of the *Bulletin*, so thoroughly discredits the tables of our contemporary that we dare not use its data, when it comes to the much more difficult task of estimating capacity.

On the whole, the statistics offered show that, while the pig-iron industry is tending toward a sounder basis, they do not give any encouragement whatever for the hope that a material advance in prices can be successfully maintained. Stocks are ample, in fact more so, in some instances, than the trade appeared generally to believe.

CORRESPONDENCE

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. We do not hold ourselves responsible for the opinions of our correspondents.]

"The Outlook for Lake Superior Iron Mines."

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: When a person seeks to teach the public through the medium of an influential trade paper, he should at least make a proper effort to obtain facts, rather than state with so much positiveness what he conceives to be facts. In his article, under the above caption, in your issue of July 21st, "Specular" says, "Generally speaking, the mines are as saleless as in January or February." Again, "It is quite probable that a few thousand tons may be sold by shaky companies for what the iron-mongers have a caprice to pay, but this disturbing factor will be transient and of little consequence." Again, "If indeed any sales thus far can be said to be important."

If "Specular" had seen fit to place himself in communication with any reputable commission house in Cleveland, he could have become acquainted with the fact that, on July 1st, at least 1,250,000 tons of ore had been placed. At this date, it is quite within the limits of safety to say that this has been increased to a million and a half of tons. To July 11th, 685,585 tons had been brought down, and at this rate by November 11th we shall have a movement of hard on to two million tons, larger than any year in the history of the trade, except 1881 and 1882. Some of the mines are entirely sold up, and are refusing orders. So far from the companies, as a rule, bringing down ore which is unsold, exactly the contrary is the case; nine tenths of the ore down is sold, and a large daily movement of ore from the dock to consumers is going on. P.

CLEVELAND, July 23.

The Luminosity of Heated Coal-Gases.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: The luminosity of the gases derived from coal depends entirely on the carbon set free and kept incandescent *during* the process of combustion. Without this condition, they cease to be illuminants. This is the case, either when carbon is prevented from separating and becoming incandescent in the flame, or when it is separated from the gas before the latter is ignited. The illuminating part of gas consists of heavy hydrocarbons, especially ethylene, C_2H_4. This, under ordinary circumstances, burns, separating carbon, which, in a state of incandescence, furnishes the light. With a greater addition of air, this carbon is not allowed to separate as such and remain incandescent, but is all converted to carbonic acid. This is the case when illuminating-gas is burned through a Bunsen burner. The lighter hydro-carbons, CH_4, always burn, *without separating carbon*, to carbonic acid and water; therefore they give no light. When a gas is highly heated before ignition, the heavier hydrocarbons are destroyed, and converted, with separation of half of their carbon, into lighter hydrocarbons, which burn without giving light. This explains the result of the practical test by Dr. Siemens, referred to under this heading in the ENGINEERING AND MINING JOURNAL, Vol. XXXVI., No. 3, p. 37. This explains also how gases which burn with separation of incandescent carbon have a greater *radiant* heat than otherwise. The incandescent carbon is the source of the radiant heat. This may easily be tried with a Bunsen burner, which will give, with closed air-holes, more radiant heat than with open. In the latter case, the heat is all concentrated in the flame, no incandescent carbon being separated, but all burning to carbonic acid. ADOLF GLEIM.

426 WALNUT STREET, PHILADELPHIA, July 21.

NEW PUBLICATIONS.

A PRACTICAL TREATISE ON THE STRENGTH OF MATERIALS; *Including their Elasticity and Resistance to Impact.* By THOMAS BOX. London and New York: E. & F. N. Spon. 1883. Small octavo, 525 pages, with Index and numerous Plates.

As the writer of practical treatises on "Heat," "Hydraulics," "Mill-Gearing," etc., and as an eminent authority on the subject o this volume, Mr. Box is already widely known; and this volume, giving the latest and best empirical rules established by English practice, as well as the theoretical laws and formulas, where these have practical certainty and value, will be welcome to all engineers. A cursory examination of the book leads us to praise its arrangement and clearness of style. It is beautifully printed, and the plates, though small, are very good. We have detected no errors of the proof-reader; and the general appearance of careful editing makes us feel pretty sure that in this particular it is free from fault. In the case of a book consisting so largely of formulas and tables, defects of that kind are disastrous; and yet they are not always detected at first examination. Mr. Box dates his preface in March, 1883, and professes to have incorporated the latest researches and experiments. Yet we can find no trace in his book of the report of the United States Testing Board, the first volume of which has been several years, and the second a shorter period, before the public, in larger editions than such books usually enjoy. In the first volume, to say nothing of other important matter, Mr. Box might have found the splendidly thorough paper of Commander Beardslee's committee on chains and cables—a discussion which no writer on that subject can afford to ignore. But we point out this deficiency rather for the benefit of English than of American engineers. In this country, we have other means of getting the results of American practice and investigation, and do not need to go to English books for them. Hence the fact that Mr. Box's manual, like so many others from that side of the water, is filled almost exclusively with English data, rather enhances its value for us. It is not we, but our British brethren, who should demand of their technical authors a wider range and greater energy. *

LIFE OF SIR WILLIAM E. LOGAN, KT., LL.D., F.R.S., F.G.S., *First Director of the Geological Survey of Canada, chiefly compiled from his Letters, Journals, and Reports.* By BERNARD J. HARRINGTON, B.A., Ph.D., *Professor of Mining in M'Gill University; Late Chemist and Mineralogist to the Geological Survey of Canada. With Steel Portrait and Numerous Wood-Cuts.* New York: John Wiley & Sons. 1883. Octavo, 432 pages. (*Index.*)

Professor Harrington, in his modest preface to this volume, represents himself as a mere compiler, and says his aim has been, not "to write a eulogium or yet a lengthy criticism of Sir William, but rather to bring together such of his own words as will recall him to the minds and hearts of old friends, or enable those who were not privileged with his acquaintance to form for themselves an estimate of his character and work." This aim, it must be confessed, is, after all, that of every worthy biography. Whether it shall be attained by compilation or by a more formal portraiture, is a question of means simply. Professor Harrington has accomplished with judgment and taste the task he set before himself. The book contains an intelligent and interesting account of Sir William Logan's work, and also reveals the character of the man, more clearly and naturally, perhaps, than this could have been done by a deliberate critical analysis.

It is pleasant and instructive to note that Logan began his career as a mining engineer and metallurgist. To use his own words, "My whole connection with geology is of a practical character. I am by profession a miner and metallurgist, and for many years was one of the active managing partners in an establishment in Wales, where we annually smelted 60,000 tons of copper ore and excavated 60,000 tons of coal." Such a practical experience is an excellent introduction to certain branches of geological work. The reverse process is not so successful. Eminent geologists do not necessarily or easily become experts in mining or in economic geology. On the other hand, it is true that those men who begin with mining, and having acquired in the practice of this art a habit of keen observation, are liable to generalize too rashly and too widely from data which are local and subordinate, as compared with the more general facts of geological science. From this weakness, Logan was singularly free, no doubt because he was already prepared by education and habits of thought to study logically the phenomena he encountered. His paper on the Under-Clays of South Wales, read before the Geological Society of London in 1840, is an admirable specimen of clear and cogent reasoning. It carried conviction with it, and settled at once and for good a most important question connected with the formation of coal. That this mineral is of vegetable origin, was generally admitted; but whether the coal-beds have been formed like accumulations of drift-wood, or have grown in the manner of peat-bogs, *in situ*, was vigorously disputed. Logan, while engaged in coal mining, observed under eighty or more coal-seams, in the Welsh field, the invariable pressure of so-called under-clay, containing *stigmaria* in such conditions as to prove that the plant had grown there and had not been drifted there. The constancy of this phenomenon, once demonstrated, overthrew the drift theory. Logan's further conclusion, that "in the *stigmaria ficoides* we have the plant to which the earth is mainly indebted" for its stores of fossil fuel was correct in one sense, and curiously erroneous in another. Later discoveries showed this supposed species to be a root, and to support the trunks of *sigillariæ*, *lepidodendra*, etc. The leaves and upper branches of these trees have been abundantly found in the shale-roofs of coal-beds. These discoveries, complementing that of Logan, have fixed the general outlines of the theory of the growth of coal, although there are points which still challenge discussion. Professor Harrington sketches the question, cites a great part of Logan's paper, and refers the reader to the works of Principal Dawson (probably the highest authority on this subject), for further details.

Logan's scientific enthusiasm exhibited itself early, in his preparation, with great labor and at private expense, of a topographical and geological map of the coal district of Glamorganshire, Carmarthenshire, and Brecknockshire. This map was exhibited by him in 1837—he was then thirty-nine years old—at a meeting of the British Association. Delabeche, then Director of the Ordnance Geological Survey, said of it:

"The work on this district being of an order so greatly superior to that usual with geologists, and corresponding in the minuteness and accuracy of its deta

Digitized by Google

with the maps and sections executed by the Ordnance Geological Survey, we felt desirous of availing ourselves of it, when Mr. Logan most handsomely placed it at our disposal. Having verified this work with great care, we find it so excellent that we shall adopt it for that part of the country to which it relates."

Such a compliment, from such a source, was equivalent to fame. The quotation is from a letter to the Colonial Office, urging the appointment of Logan to the Geological Survey of Canada. Murchison, Sedgwick, and Buckland heartily joined in this recommendation; and in 1842, the appointment was made, and Logan undertook his "herculean task," as Sedgwick had called it. This constituted the great work of his life. Of the manner in which he discharged it, we will not here speak at length. Professor Harrington's book gives an excellent summary of the progress of this great survey, not omitting to recognize with unstinted praise the labors of those who, like Murray and Hunt, so ably supported their energetic chief. Moreover, an appendix, from the skillful and graceful hand of Principal Dawson states with welcome clearness the disputed questions concerning the age and stratigraphical relations of the Quebec group, regarding some of which, as our readers are aware, Dr. Selwyn, the present director of the Canada Survey, has been led to reject the earlier views of Logan. Such a reversal by later and more extended research implies no discredit to the industry or acuteness of a pioneer. The work done by Logan for Canadian geology and for the development of Canadian industries will continue to be as well recognized and as highly esteemed as when in 1856 he was knighted by the Queen, and received from the Geological Society the more distinguished honor of the Wollaston medal.

Of all these matters, and of many others, such as the Lake Superior controversy, and the *Eozoön Canadense*, the reader will find the story well told in Professor Harrington's book, which is thus at once a charming biography, and a valuable record of scientific progress. *

THE BELT COPPER MINE.

Special Correspondence of the Engineering and Mining Journal.

The Belt Mines Company is a property owned and operated by English capital, and consists of the combined estates of the old Bohemian and Great Western companies, together with a sufficient territory some distance away (the Penn property) to make a round total of nearly 3500 acres. The mines are situated in the Greenland District of Ontonagon County, Michigan, which extends in an easterly and westerly direction from fourteen to twenty miles from the mouth of the Ontonagon River. They have been brought into the foreground lately by a series of representations in local and English papers, which, so far as they have any influence at all, can have no other effect than to mislead and discourage the investment of capital, and particularly foreign capital, in mining operations in this country, and therefore ought to receive a discussion which shall be fair to all parties and at the same time try and save our peninsula from the reproach of disreputable and illegitimate scheming. We can not afford to try the experiment of an Emma mine swindle on Lake Superior; for although the elastic consciences of a few well-remunerated individuals might not suffer very considerably from the tension, it would be certain to distort the reputation of our mineral fields, for many years characterized by strict integrity, into a synonym for deceit and fraud. Your correspondent does not wish to uncover any sores, or to engage in any sparring match with either friendly or unfriendly editors, when he undertakes to undeceive the foreign readers of the ENGINEERING AND MINING JOURNAL concerning the Belt mines, and he will therefore honestly endeavor to be so plain that the wayfaring man, though a foolish speculator, need not err therein. No one, unless he be willfully wrong-headed, shall misunderstand.

The Evergreen range mines were among the earliest worked on Lake Superior, some of the charters being contemporaneous with the Minnesota, the bonanza mine of twenty years ago. After several years' trial, however, these properties gradually suspended operations, from lack of cupriferous returns, and the merciless tributor was turned into them to make himself fat on whatever was left as spoils. It is about thirteen years since the Evergreen Bluff closed down, and about eleven since the National followed suit. Of late years, little or nothing has been doing in this western "Sleepy Hollow," and its very name has become the acknowledged synonym for stagnation. But during the past two or three years, there has been a resurrection from the dead of interest in this venerable county, in some purposes for legitimate development and in others for Israelitish speculation. We shall arrive at the status of the Belt mines by considering the motives behind the curtain for this revival.

It has been held that the mines of Ontonagon have not had a fair chance; that the methods of operating them were primitive and meager; that the system of labor was as ruinous as it was dishonest; and that the whole business was carried on for the interests of the laborers, and not, as nowadays, for the stockholders. And each of these charges can be successfully maintained. Certainly, the methods of breaking, hoisting, and treating rock were most primitive and meager. Operations were often confined to extracting in summer the hundred or two tons of mineral which had been discovered in the winter. The rock was treated by stamps and wash-houses of a style so primitive as to suggest a transition to the dark ages to one who visits the mills of Lake Linden and the Atlantic or even those of Copper Falls (modern), Allouez, or Portage Lake. Indeed, so much copper was lost by inadequate slime treatment that it has been thought profitable to purchase the sand-heaps of the older mines and send them through the scientific apparatus of our times. Secondly, the system of labor was essentially dishonest. No laborer had any moral compunctions that he ought to do a full day's work for a day's pay. Particularly was this true of contract miners. The hours of labor were generally eight, and even for this short shift it was seldom thought necessary to work with any thing like the regularity and pressure which characterize modern mining. It excited neither surprise nor comment if a party of miners lost the greater part of a shift, particularly if pay had been good, in order to take a turn at the town tavern. This was a fault of the times. It was equally true of the Keweenaw mines, where the contract miners by no means infrequently came up from underground, after the bosses had once "turned in," and went over to Eagle River or Eagle Harbor for a night's spree. Thirdly, the mines appear to have been operated at that epoch in the interest of the laborers and not of the stockholders. The shiftlessness of the contract work is proof positive of this, to say nothing of the silver which was appropriated by those in power, as well as stolen by wholesale by the operatives and sold to the disreputable dealers who used to put in at Copper Harbor, Eagle River, and Ontonagon. The unwritten history of these times shows a state of things which were in themselves dishonest, and not infrequently disreputable. Your correspondent does not wish to magnify this mole-hill, though it is a very formidable one, into a mountain, and therefore does not even insinuate that the system of pillage was universal, though the loose system of working was well-nigh so; for he well knows that superintendents of these properties, and particularly of the Evergreen range properties, were honest and intelligent, and would have done better if they could. The evils were an integral part of their times, and existed in the nature of things, in spite of the best intentions. But good intentions did not help the stockholders any, and the mines gradually succumbed to the incubus upon them. The introduction of labor-saving machinery, scientific treatment, high explosives, a different system of management, and a more rational spirit of enterprise has now cut off these abuses, and that forever. For the mines of Ontonagon to copy after those of Houghton in materials, methods, and vim, would be to give them what they have not as yet had, a fair chance to pile up fortunes for the holders of their certificates of stock. One Ontonagon mine, and that a neighbor of the Belt on the Evergreen range, has undertaken to solve the problem, and is the most successful mine of our day on the range. This is the argument of those who favor a revival of mining in the old properties of "higher point."

On the other hand, there were several circumstances which were favorable to a transient success. The price of copper was twice and sometimes three times as high as at present. If prices were now what they were in 1865, when the average was above thirty-six cents, the profits in copper mining would now contrast very favorably with those on iron mining during the years 1881 and 1882. Then, again, the mines were scalped, "scrammed" they call it in the iron country, the best leads being followed until they failed to pan out, when the property was summarily abandoned. Thus with the National and partially with the Evergreen Bluff. No such risks were ever taken as are now constantly taken in the Pewabic, the Allouez, or the Copper Falls; no such stretches of lean ground were attacked, and the Mars, which is the leader of the Ontonagon mines, even in this enlightened day, attempts nothing at all problematical—a thing which is not at all to its praise. Nothing problematical has yet been attempted—a very important fact—and, judged by modern standards, Ontonagon may even now be safely called a *terra incognita*. A candid discussion of this topic during the past few years, by the best copper miners in Lake Superior, has resulted in a disagreement of opinion, some holding that, with modern machinery, modern discipline, and modern vim, the best mines of Ontonagon could, if copper maintained a pretty good price, be made to pay a moderate rate of interest on the enormous outlay of capital which would be necessary from the first for conducting operations. Others, and they are legion, have not believed it would pay. And even the most sanguine have never betrayed any symptoms of enthusiasm—except, indeed, when they had a property to sell. So far your correspondent has spoken with candor, and, he trusts, with accuracy. His own modest opinion, taken for what little it is worth, is that, if copper stays at a reasonable figure, the best mines in Ontonagon, by a very liberal expenditure for underground openings, machinery, and management, can be made to yield a fair rate of interest on the capital originally invested; but that it will not at all pay, with the present outlook of the copper market, to undertake this tremendous preliminary outlay in the poorer lodes, may safely be taken as a foregone conclusion. But here we trench at once on the matter of the Belt mines.

No one knows that the Belt mine is one of the *best* mines in Ontonagon, and therefore its future is entirely enigmatical. To see representations to the contrary from interested parties, which representations are for the sole purpose of deceiving the English stockholders by positive assurances into the immediate expectation of a mine like the Quincy, is monstrous and despicable. Any and all such representations concerning the immediate dividend-paying value of the mine are the grossest fabrications, and are an unmitigated humbug. But we anticipate our historical narrative.

The Bohemian was formerly owned by Philadelphia people, who sold it for no more than $45,000, and who betrayed very marked symptoms of eagerness to part with it at that figure. The Great Western, which, with the Bohemian, comprises the present working part of the Belt property, did not bring more than its neighbor. The Penn, embracing nearly 1500 acres, sold to the syndicate for not much over $20 per acre. These estates were massed together and sold to English capitalists for $850,000. (London *Journal*.) It now appears that, to effect this sale, the most monstrous statements (I will call them no worse names) were resorted to. It was said that, with a liberal outlay of money, the mine would compare favorably with the Quincy, which has two conclusive answers: first, the party making the statement owned a very important part of the real estate which forms and was sold in the Belt transfer; second, the property which the party recommends as being a rival of the Quincy sold for a trifle over a single hundred thousand dollars, while the Quincy is worth $2,000,000. During its entire thirteen years' working, the Bohemian has produced an aggregate of only 216 tons, while the Quincy averaged much more than that every month of 1881, and, I think, 1882. Of course, it is not understood that the Belt is to rival the Quincy alone in expenditures, for that represents an outgo of nearly $15,000,000. The point is here: the Belt property has not been tested, and therefore its value is unknown. When the communications were sent to England that the property could be brought to pay $200,000 annually inside of two years, less than a single hundred feet had been sunk on the Knowlton vein (an entirely new ven ture), and less than sixty feet in the Bohemian on the Butler or Champion vein. Not even the beginning of a drift had been commenced on the Knowlton vein, and less than seventy feet had been driven in either of the two old levels of the Butler vein. These facts carry their own inference. No adequate mill test of the work had been made, and the persons who, in the early part of the transaction, recommended the mine as a rival of the Quincy, to say nothing of laying on the chunk which broke the camel's back by comparing it with the Calumet & Hecla, knew

Digitized by Google

as little of the cupriferous contents of the mine as they knew of the contents of Sirius or the Pleiades.

No one knew, dear lambs, no one could know what the mine could do. One who was entirely familiar with the old Bohemian remarked to your correspondent that it was too lightly charged with copper to pay for treatment and handling; but this must not be taken for more than it is worth. The mine may be able to pay something, certainly has some copper in its epidote formations, and I do not wish to throw suspicion upon it. No one knows, however, and those who pay for its stock and remit its assessments ought so to understand. If, under the circumstances, they are willing to undertake the very expensive development of the property, it is well, and their enterprise is most commendable. But honestly, it will be as useless, at the present rate of development, to expect any thing at all in two years, as it will to expect ever to receive such returns as are made by the Quincy, which in turn will be as foolish as to expect the tides to sweep the bars of ingot from the depths of Lizard and Eddystone into the harbors of Cornwall.

One further word: An enormous outlay of capital is making, a mill of Ball stamps and improved washers for treating the Belt rock. I learn, from a recent and interesting article by the editor of the Hancock *Journal*, that preparations are making for laying in a plant of hoisting and compressed-air machinery, though I have obtained no information at this writing when this will take place. It is, as yet, a mystery to what use this elaborate pile of machinery will be put, particularly if the present rate of progress be kept up. The Atlantic sends as much rock through its mill in fifteen days as the Belt has hoisted for openings in its whole thirteen years' operations. The Osceola opens up every two months as much as the Belt (Bohemian) has opened up in its entire history. The Copper Falls was organized at the same time with the early Ontonagon mines, and for a season was dividend-paying; but, although it has the advantage of modern machinery, methods of labor, and efficient management, it has long since ceased to pay any dividends. Six hundred and twenty thousand dollars have been paid in assessments, independently of the original subscription, and I am informed that a new one of $60,000 is being quietly handed in. It has paid precisely $100,000 dividends in its twenty-eight years' existence. If modern machinery could make a Quincy or a Calumet & Hecla out of all the profitable mines of the Bohemian's day, the Copper Falls stock would be worth several hundred dollars per share. As it is, they are not cheap at one.

And finally, your correspondent has written these words of truth and soberness in the kindest humor, and has set down not one thing in malice. He joins the editor of the Hancock *Journal*, in hoping that the mine will richly repay the vast outlay of money which has just begun to be made, and which must be continued for a long space in the future before the mine pays, if, indeed, it ever pays. That the property has been ignorantly or maliciously misrepresented is certain; for no one knows what it can do, nor will he know for some time to come.

SPECULAR.

THE TRANSPORTATION OF HIGH EXPLOSIVES.

NEW RULES FOR THEIR SHIPMENT.

Commissioner J. W. Midgley has issued the following circular, under date of July 21st, for the use of the railroads in the Southwestern Railroad Association, Iowa Trunk Line Association, and Colorado Traffic Association:

Shipments of Hercules powder, Atlas powder, giant powder, and other explosives of which nitro-glycerine forms the basis, when subject to the above associations, except California, will hereafter be transported on the following conditions and at the following classification:

1. That, at the cost of shippers, the bottom of the car containing the above-mentioned explosives must be covered to the depth of at least two inches with sawdust, to absorb possible leakage.

2. That the packages containing the explosives shall be so placed and loaded that the cartridges shall always lie on their sides and not on their ends.

3. That the cars shall be so marked, on both sides and ends, that those who will have charge of them will not do any thing ignorantly to incur danger.

4. In less than car-loads, this property will be received (when made into cartridges only, and not in bulk under any circumstances) on the following conditions:

Packed in wooden cases, in cartridges, each case not exceeding 100 pounds, nor less than five pounds of explosives, provided that such explosives are packed in dry sawdust, as follows:

Each cartridge shall be surrounded on all sides with dry sawdust, and all interstices between such cartridges and a space of least one inch between the outer side of such cartridge and the inner side of the case shall be filled with dry sawdust. Each of these cases shall be plainly marked on at least three of its sides with the name of its contents and "Explosives—Dangerous," so as to be readily seen by those who are to handle it.

5. In no case must the caps, fuse, or exploders used for exploding these powders be loaded in the same car with the explosives, and under no circumstances will the cars be received if so loaded.

6. Any and all nitrate or other explosive preparations not in accordance with such specifications (except ordinary black powder) will in no case be received for shipment.

7. All loss or damage to such property that may result from explosion or from a disregard of any of the above conditions by shippers or by the agents of the lines comprised in the above associations must be assumed by the shipper or owner.

8. Under the above conditions, the rates will be: In quantities less than car-loads, actual weight, twice first-class; in car loads, actual weight, minimum 20,000 pounds per car, first-class. No shipment will be rated at less than 100 pounds.

The right of any of the railroad companies comprised in the above associations to refuse to receive high explosives for transportation under any circumstances is reserved.

This circular is a most important one, as heretofore high explosives were not mentioned in the tariffs of these associations, being accepted by the different lines at special rates.

MINING IN CALIFORNIA.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Mining in California may be said to be unusually dull. We hear of but few new enterprises, and of no great successes to mark this season. You have heard, probably, of the sale at last of the Providence mine of Grass Valley to a French company. The price paid for it is said to be $1,200,000, of which 25 per cent is in stock of the new company and $140,000 are to be placed in the treasury for working capital. The purchase includes the adjoining extension claim. A new sixty-stamp mill is to be erected, giving, with the present mill, eighty stamps in all. The estimates of production are made in the usual way, on paper, by multiplication.

Assuming that the quartz will net $8 per ton, and that the mill will crush 200 tons a day, it follows that the net daily product is to be $1600, or close upon half a million a year—a brilliant and beguiling estimate, the realization of which need not be expected. *Nous verrons.*

The sale of the Drum Lummon mine, by Thomas Cruse, to English parties is still the topic of conversation in mining circles. This mine, you are aware, is about twenty miles from Helena, Montana, and has been worked for gold. Cruse is said to have taken out over $125,000 with the aid of a five-stamp mill. The new company is known as the Montana Company, Limited, and has appointed George Attwood, F.G.S., general manager. Extensive and costly preparations are making for working the property on a large scale. The firm of Prescott, Scott & Co. is now constructing an air-compressor of unusual size for this mine.

The Pacific gold mine, of Amador County, which adjoins the Empire, appears to justify the expectation of its value based on the development made in the Empire at and beyond the line. The two properties are now consolidated, and a dividend has been paid. The Pacific shaft is to be sunk to a depth of 1300 feet.

The iron furnace at Clipper Gap, near the railroad in Placer County, which was burned last year, has just been started up again. The iron produced is excellent in quality, especially well adapted to the manufacture of malleable iron castings and of steel. A fine quality of chilling iron is also made, and is now used by the Central Pacific Railroad Company for the manufacture of car-wheels at the Sacramento shops.

Preparations for malleable iron and steel-works at the Bay are now well advanced, and they will be in operation by the first of October or before. Charcoal is abundant and cheap at the mine. This iron and steel enterprise is largely controlled by Mr. Irving M. Scott, of the Union Iron-Works, whose energy, enterprise, and public spirit give assurance that it will be one of the growing and permanent industries of the Pacific coast.

The lead and silver smelting-works of the Castle Dome Company, at Melrose, are in constant operation, and turn out from 250 to 300 tons of refined lead per month, used chiefly for corroding.

The Silver King mine has passed its usual dividend, owing in part to the interruption of the mining by the extremely hot weather, which so impaired the ventilation as to prevent the miners from working. The seventh level is still productive, but a part of the ore is not up to the usual standard. The shaft has been sunk to the eighth; but owing to the lack of ventilation, the drift could not be run into the ore-body. Until recently, a scarcity of water prevented running the mill to its full capacity.

GLÜCK AUF.

SAN FRANCISCO, July 10.

THE PRODUCTION OF COAL IN THE WORLD.

M. Paul Trasenter, of Liége, who is rapidly acquiring the reputation of one of the leading statisticians on mining and metallurgy, has recently collected the figures for the production of the leading countries in the world. Those who have attempted work of this character appreciate the difficulties with which such compilations are beset. It is gratifying to note that the governments in all the leading countries are now making efforts not only to carefully collect the data, but also to get them as rapidly as is consistent with reasonable accuracy. In past years, it was no uncommon thing to have official statistics published from one to three years late; while in other countries, private enterprise had to supply the gap. For a number of years, the figures have been collected in a very desultory way here. This, we are pleased to note, will now end through the enterprise of the United States Geological Survey, and the industry of Mr. Albert Williams, Jr., the chief of the Department of Industrial Statistics. We believe that M. Trasenter's figures in the following table for the years 1879 to 1882 will prove rather too low; but we give them as they stand, adding that the unit is a million metric tons:

	1860.	1870.	1873.	1879.	1880.	1881.	1882.
Great Britain	85·4	112·2	129·0	135·8	149·3	156·6	158·8
United States	15·2	30·7	51·3	63·8	70·3	77.3	88·1
Germany	12·3	34·0	46·1	53·6	59·2	61·5	65·4
France	8·3	13·1	17·5	17·1	19·4	19·9	20·8
Belgium	9·6	13·7	15·8	15·4	16·9	16·9	17·5
Austria-Hungary	3·5	8·3	11·9	14·9	16·0	17·3	18·0
Totals	134.3	212·0	271·6	300·5	331·1	349·5	368·6

In order to complete the record, the following figures are added for a number of countries of minor importance, whose statistics are not complete or not recent:

Russia (1881)	3,245,000 tons.
Spain (1881)	1,171,000 "
Sweden (1881)	120,000 "
Australia (1881)	2,200,000 "
Canada (1881)	1,437,000 "
British India (1880)	1,030,000 "
Chili (1880)	800,000 "
Japan (1879)	530,000 "
China (estimated)	3,000,000 "

Counting the probable production of uncivilized countries, we reach a total production in the world of about 385 millions of metric tons of coal and lignite, which, of course, is not at all apportioned in reference to the narrow extent of the coal territory. Thus, two thirds of the output comes from 15,400 square miles of coal-fields in Eastern Europe, while the coal measures of Russia underlie 19,300 square miles, those of British India 34,740, of the United States 180,000, and of China 520,000 square miles.

The development has been more striking in the United States during

Digitized by Google

the past two decades, 1882 showing an output more than six times as great as 1860, while the capacity has probably increased fully sevenfold. Great Britain has barely doubled its yield; while Germany, with its limited area and deep mines, has made progress with a rapidity only equaled by our own. It should be remembered, however, that one fifth of the product is lignite, of a quality which can not take full rank with good coal. France has done well, but is not, from the limited area of its coal-fields, likely to assume a relatively more important position. Belgium, the most intensely active section of the continent industrially, is also bound to lose ground in the race; while Austria, though having a wealth of lignite, which constitutes three fifths of its output, can not boast of great resources of coal.

How much room there is for an expansion of the coal trade in this country may be gathered from a contemplation of the comparative consumption per capita in the different countries. In England, it is 8686 pounds per inhabitant; in Belgium, 5093; in the United States, 3637; in Germany, 3065; in France, 1808; and in Austria, 948 pounds. When the United States has become, like Great Britain and Belgium, one of the workshops of the world, instead of being, as now, restricted to home industries looking only to local markets, and when the domestic consumption of wood as a fuel has been reduced by the cheapness of coal and the growing cost of wood, we shall be the greatest coal producers in the world.

How great are the advantages we possess by the accessibility of vast areas of coal-beds of comparatively great thickness, may be gathered from the following comparative figures of the yield of coal per miner per annum: The United States heads the list with 400 tons, followed by England with 345, Germany with 261, France with 186, Austria with 170, and Belgium with 166 tons. We venture to say, however, that, on the other hand, there is no country in which, not only absolutely but relatively, the wages paid to coal miners are as high as in this country. No one will desire to see this state of affairs changed; but we believe that it should be fully understood that, taken as a whole, the miners share more fully in the profits of the business here than they do anywhere else, and that their receipts far more than counterbalance the difference between the yield per man per annum between the United States and Great Britain, for instance. Another factor which tells against our mines indirectly, by increasing the cost to consumers, is the long haul to market, a fact which is aggravated by the circumstance that coal is usually made to pay profits not alone on watered capital, but also to compensate for the necessarily low figures at which agricultural products must be carried to export points to compete in foreign markets. Against the former, the coal interests have a right to protest vigorously; but they have, on the whole, little objection to the latter, provided that it is fully understood by the agricultural interests that the coal producers are indirectly affording them the means of advantageously marketing a surplus. When their would-be champions attack the manufacturing industries of the country, and are met with the plea that fuel is high, they have no right to make a raid on the miners and shippers of coal who pay the carriers of wheat, corn, and provisions a round share of their profits.

THE LAW AS AFFECTING MINING AND METALLURGICAL INTERESTS.

Abandonment of Claims as Affecting Later Applications.—The following letter was written by Secretary Teller to the Commissioner of the General Land-Office:

I have considered the claim of Marcus Daly, involving mineral entry No. 924, Helena, Montana, made December 14th, 1882, upon the Rob Roy lode, lot No. 147, submitted by your letter of the 23d ultimo, for the action of the Board of Equitable Adjudication, as provided by sections 2450–2459 of the Revised Statutes, as amended by the act of February 27th, 1877. The facts which control your action are as follows:

Daly's application covers 0·17 of an acre, which is included in lot No. 57, for which an application had previously been filed by one David Upton for his claim upon the Lookout lode. It also covers 0·13 of an acre, embraced in the placer claim of Josiah Burchett, whose application antedated that of Daly. Neither of the owners of the Lookout lode nor of the Burchett placer offered any opposition to Daly's application, which was filed in the local office March 16th, 1882, and notice of which was duly posted, as required by law. On the 1st of November, 1882, Burchett executed in due form before a notary public an abandonment of so much of his placer claim (describing by notes and bounds) as conflicted with the Rob Roy claim, which abandonment was on the 7th day of November, 1882, placed on record in the office of the Recorder of Silver Bow County. Upton, claimant of the Lookout lode, was adversed by the claimants of the Anaconda lode, lot No. 92. Instead of resisting the adverse, he, on the 6th of October, 1882, duly executed an abandonment of his entire claim, which abandonment was placed of record in the county, October 9th, 1882.

This left the Rob Roy claim without any conflicting application, and the register and receiver, therefore, accepted the money in payment for the ground, and allowed the entry.

You, however, decline to issue patent, the objection being the existence, at the date of Daly's application, of the prior application referred to. The theory of the objection, as I understand, is, that the earlier applications of Upton and Burchett operated to segregate from the public domain the ground covered by their respective claims, and consequently rendered it, or any portion of it, unavailable under the application of Daly, notwithstanding the abandonment of Upton and Burchett. It is true that the effect of an application duly filed may be regarded as a segregation and appropriation of the land conveyed thereby, and that the natural result of an abandonment would be the reversion of the ground to the domain from which it was carved. But where, as in this case, two applications, covering in part the same ground, have been made and accepted, and the one first made has been abandoned, either in whole or as to the portion in conflict, it may, I think, be held under the law that the ground in conflict falls within the purview of the second application and becomes subject thereto. There is nothing in the mining laws to preclude this view, and if there is any thing in the regulations which would by implication tend to prevent such a course, the department may, in a case like this where no one can possibly be wronged by such action, waive its regulation to the extent and for the purpose indicated.

I therefore do not regard a reference of the case to the Board as necessary. Daly appears not only to have acted in good faith, but to have complied with the law in every particular. His claim is now entirely free from conflict. The question at issue is solely between him and the government. No one else is interested. His money has been tendered and accepted in payment for all the ground covered by his application.

No other vested right by purchase has been secured. This department has full jurisdiction to permit or refuse an entry of the land. You hold upon these facts that he has only an equity for the issue of patent. Hence your reference to the Board.

But, for the reasons given, I am of the opinion that the whole case is clearly within the jurisdiction of this department, and that there is no valid objection in law to the granting of patent as asked.

The government, by allowing the two applications for the same ground, may, although the register and receiver erred in allowing the second, be regarded, in considering its own action, as having removed itself two degrees from a full and complete ownership in the premises; and when the superior title fails, by abandonment or otherwise, the inferior may then be recognized and treated as valid, the law having been fully complied with by the applicant.

E. C. Ford, Esq., acted as counsel for Daly in this case.

Lode versus Placer Claims—the Mike & Starr versus *Iron Silver.*—Secretary Teller has rendered the following decision in this case, in a letter to the Commissioner of the General Land-Office:

I have examined the matter of the survey of the claim of the Mike & Starr Gold and Silver Mining Company upon the Gardner lode, . . . Leadville, Colorado, on appeal from your decisions of July 7th and September 16th, 1882, by the former decision holding such entry for cancellation, and by the latter declining to change the former. You held the entry for cancellation because the lode "claim lies completely within the limits of the Moyer placer, . . . which was patented to William Moyer January 30th, 1880," and because by the issue of such patent "the Land Department had exhausted its jurisdiction."

Sec. 2333 of the Revised Statutes provides that, where a vein or lode "is known to exist within the boundaries of a placer claim, an application for a patent for such placer claim which does not include an application for the vein or lode claim shall be construed as a conclusive declaration that the claimant of the placer claim has no right of possession of the vein or lode claim."

Since your said decision, I have held, in construing this section of the statute, that the effect of said section was to carve out of a patent to a placer claim all lodes known to exist at the date of the application, together with twenty-five feet of surface ground on each side. (Becker *vs.* Sears; War Dance *vs.* Church Placer; Mammoth Quartz Mine, Robinson claimant, *vs.* Royder; Shonbar Lode, Barret claimant.)

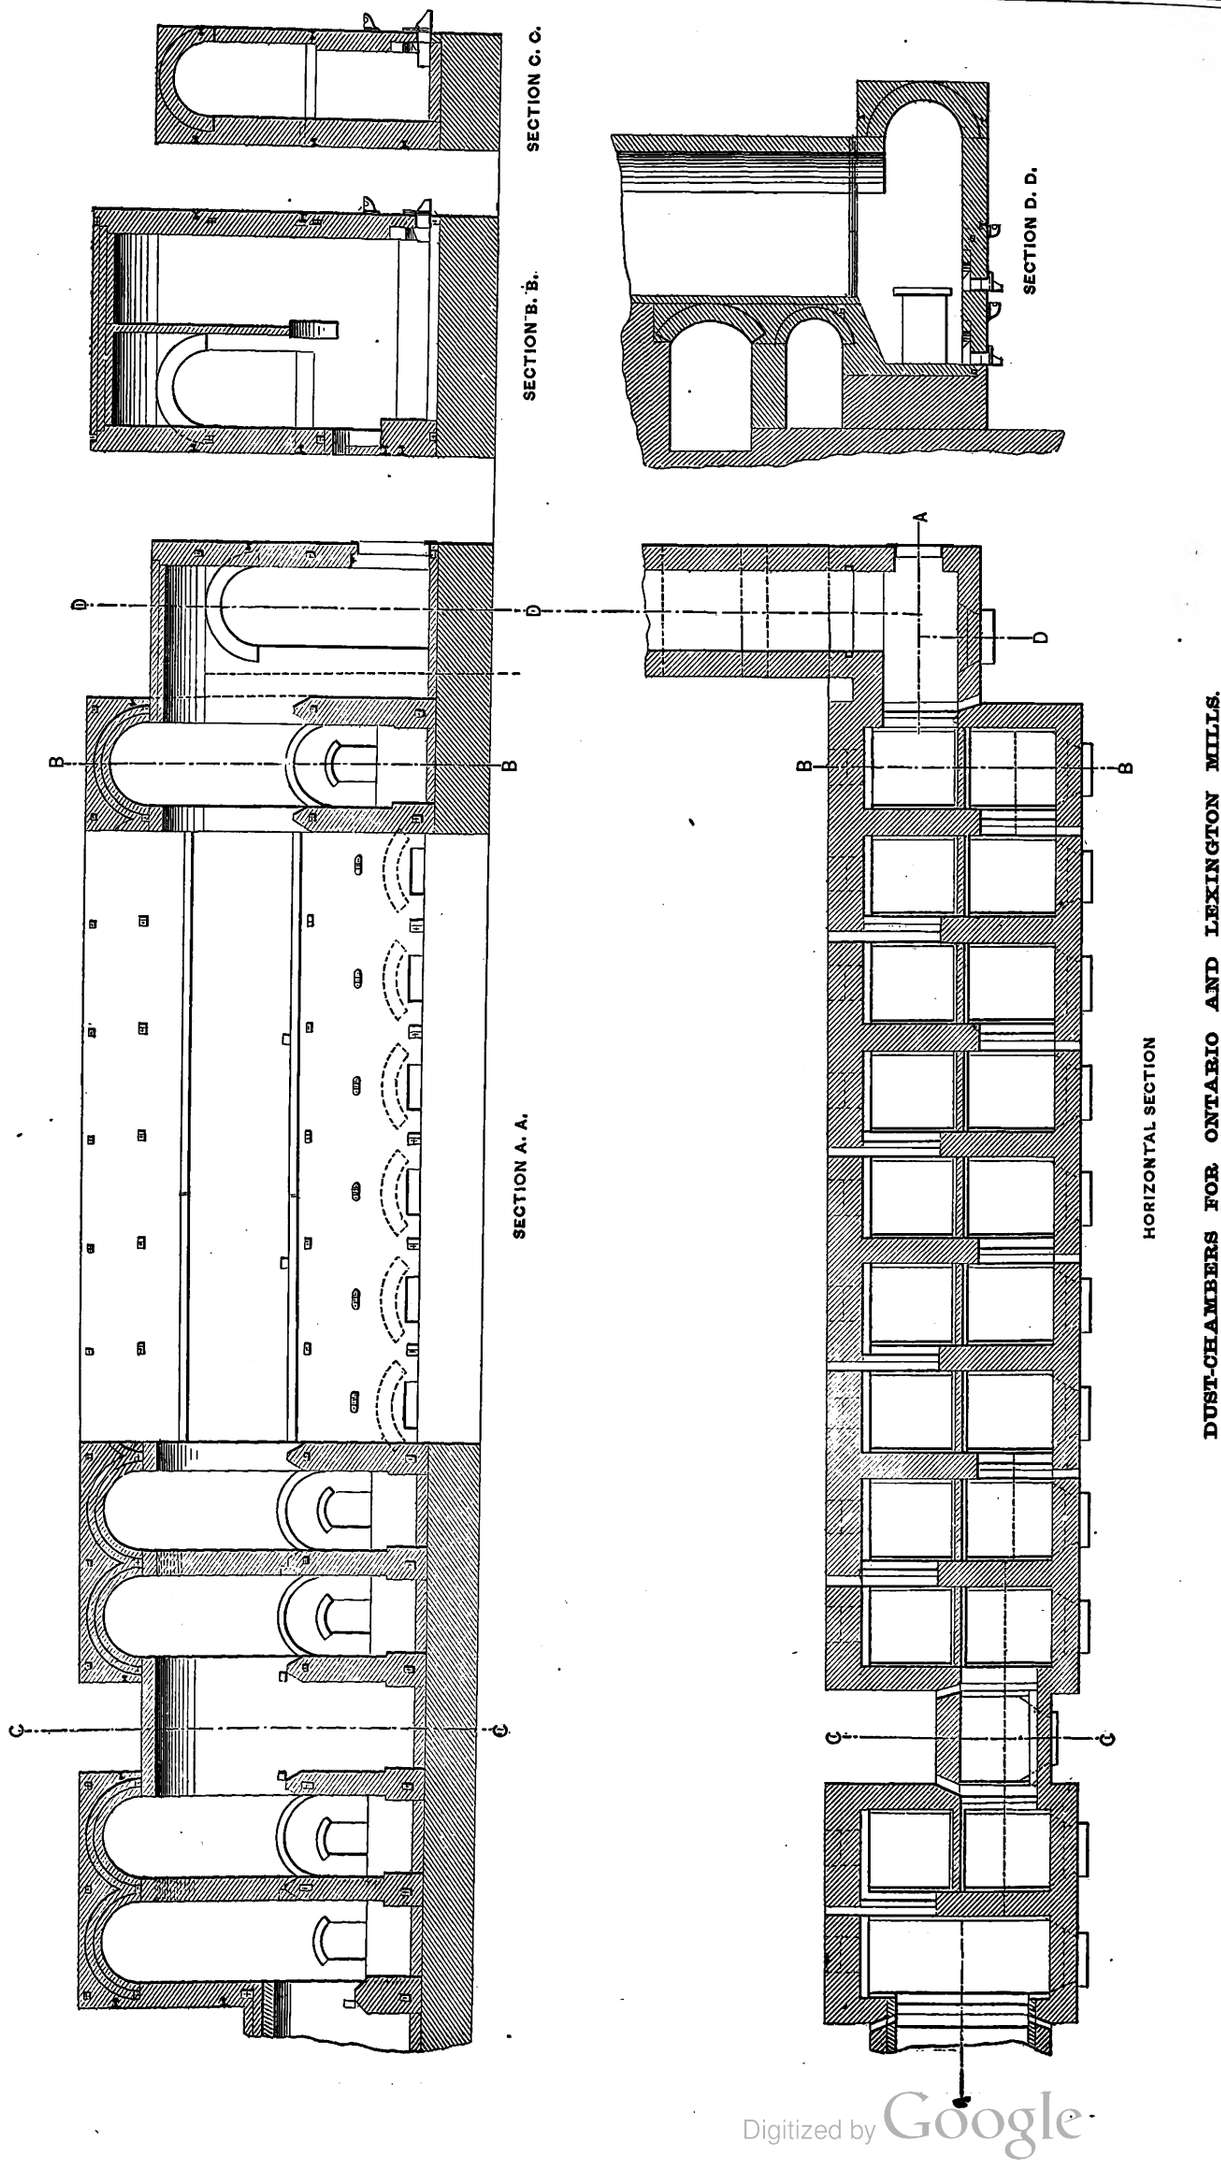
The mere fact that the placer patent to Moyer by description covers the same ground does not deprive the Land Department of jurisdiction nor prevent it from issuing a patent for a lode within the exterior boundaries of the placer. (Rico Town-Site Case.)

If, in fact, a lode was known to exist at the date of the application for a patent, the statute excepted it out of the placer patent. In the patent issued by your office to Moyer for the placer in question, you excepted and excluded such lode, if known to exist, in the following language: "Should any vein or lode of quartz or other rock in place, bearing gold, silver, cinnabar, lead, tin, copper, or other valuable deposit, be claimed or known to exist within the above-described premises at the date hereof, the same is expressly excepted and excluded from these presents."

In the cases cited, I held that the lode must be known to exist at the date of the application for the placer claim. The date of the Moyer application for patent was November 13th, 1878. The application for said Gardner lode states that it "was discovered and located" on or about the 10th day of March, 1879.

Upon the motion for the rehearing before you, three affidavits were filed, which tend to prove that, by means of a tunnel, constructed in 1876 and 1877, the mineral vein now known as the Gardner lode was discovered in 1876, and that said Moyer, at the time of his said application, knew of said tunnel within the limits of the ground included in his application, and that mineral had been discovered therein. The discovery of the mineral is denied.

The Mike & Starr Company asks that the entry of the Gardner lode be allowed to stand, and that a hearing may be ordered at the local office to determine whether such lode was known to exist.



The Iron Silver Mining Company, the present owner of said Moyer placer, has placed on file and called my attention to a newspaper report of a decision, rendered the 18th ultimo by Judge McCrary, of the Eighth United States Judicial Circuit, in the case of said company *vs.* Sullivan *et al.*, in a conflict between the Wells and Moyer placer claim and the Kit Carson and Brooklyn lode claims. The report states that the court "held that the term 'known lode or vein' within Section 2333, which was reserved out of the placer patent grant, meant a known lode or vein mining claim which had been duly located or recorded and owned by some third party before the application was made for the placer patent." No official copy of the decision has been received by this department; but since the material question at issue in this case is being considered by the courts of the district in which the property in dispute is located, I deem it best for all parties that the controversy should be determined by the courts rather than by a hearing at the local office. The application in this case is for 1500 linear feet, with 300 feet surface ground; and notice of application was so published. It will be seen, by reference to decisions already cited, that the claim can not be allowed to that extent.

The application therefore must be dismissed, without prejudice to the claimant being permitted to proceed *de novo*. Should the claimant elect to proceed, "he must be required to show affirmatively the existence of such mine, and its true location, and prove his possessory right and value of work performed," and in all respects show a compliance with the law relating thereto. The adverse claim can then be made, and the controversy determined in the courts, as before indicated.

I reverse your decision.

The case of the claim of the Mike & Starr Gold and Silver Mining Company upon the Goodell lode, ordered by the Commissioner of the General Land-Office to be canceled because found to lie completely within the limits of the Moyer placer, is determined by the above decision, and the commissioner's decision is reversed, and the same direction given.

NITROGEN IN COAL.

The cheaper production of ammonia is just now the favorite study of more than one chemist. The gas, as most of our readers know, is a compound of hydrogen and nitrogen. Both of these occur in coal. During its destructive distillation in close vessels, as in the ordinary process of gas-making, more than sufficient hydrogen is liberated to combine with all the nitrogen present. Unfortunately, the problem is, how to get that nitrogen out. A good deal of misapprehension exists on the subject, and so well-known an authority as Professor Roscoe states, in the latest edition of his *Text-Book on Chemistry*, that the whole of the nitrogen is, as a matter of fact, given off from the coal. It seems to have been reserved for Professor Foster to show that this is a delusion; but he has not yet advanced beyond this purely negative point. A sample of Durham coal, subjected to destructive distillation in gas or coke-ovens, gives off only about a seventh of its nitrogen. As every hundred parts only contain 1·7 parts of nitrogen, it is obvious that the total quantity obtained is not large, and any process which would increase it would be of enormous importance to commerce. A small portion of the lost nitrogen combines with the carbon of the coal to form cyanogen. This is removed in the usual course of purification to which gas is exposed, but the nitrogen thus evolved is of course wasted. Another portion of the original store contained in the coal remains in the free state in the gas, just as it does in larger quantities in ordinary atmospheric air, and this, again is, commercially speaking, of no manner of use. A fourth installment is left behind in the coke. Thus, when we come to inquire where the original supply of nitrogen in the coal has gone to, we find that very little of it is available for the production of ammonia, and that every hundred parts of the elementary gas are thus disposed of:

Nitrogen of the coal evolved as ammonia in ordinary distillation..	14·50
Nitrogen of coal evolved as cyanogen.....	1·56
Nitrogen of coal which is present in the coal-gas in the elementary condition.....	35·26
Nitrogen remaining in the coke.....	48·68
Total	100 00

These are laboratory results, so to speak—that is to say, they were obtained by special analysis; but it is noteworthy that they do not differ from those attained in the common preparation of gas. It comes to this, then: that, so far as all known processes are concerned, only a quarter of one per cent, or ·25, of the coal comes off as nitrogen, and 1·5 per cent, which the coal undoubtedly contains, is entirely wasted and lost. It is only necessary to state the problem in order that its bearing, not only on the production of the ammonium salts of commerce, but also on the economical use of coal, should be properly felt and adequately studied.

ON DUST-CHAMBERS.

By C. A. Stetefeldt, New York.

Prof. T. Egleston read a very interesting paper at the Boston (February) meeting of the American Institute of Mining Engineers, on the collection of flue-dust at Ems. After describing the successful experiments carried out by Mr. Freudenberg, he remarked, "These experiments have demonstrated the importance of surface over volume," in collecting and settling dust. While the Ems construction of suspending a large number of sheets in a flue, to create a maximum of surface, is undoubtedly new and original, the correctness of the principle has been known to me since 1873, and has been demonstrated in dust-chambers constructed for the Stetefeldt furnace. Without publishing any thing on the subject, I have frequently drawn the attention of metallurgical engineers to the facts, most of whom, however, did not seem to comprehend their practical importance.

It is but natural that I should have given considerable attention to the construction of dust-chambers in the erection of Stetefeldt furnaces, where the complete collection of dust is of vital importance. In erecting the first furnaces at Reno, Austin, Mineral Hill, Belmont, and Belleville, all of which were built in Nevada, in quick succession, I followed the old notion that, by lessening the speed of the current, the fine particles would settle. In every instance, however, I had added a system of narrow chambers. Very soon, I discovered that the amount of dust collected in the large chambers was very slight compared with their volume, and that more dust settled in contracted places—for instance, under the damper at the end of the chambers, and wherever the current was forced to move around a sharp corner and strike a wall. I then abandoned large chambers entirely, and adopted the construction as carried out at the Ontario mill, Utah, and the Lexington mill, Montana, for Stetefeldt furnaces; and also at the Alice and Silver Bow mills, Montana, for Howell furnaces. It is represented in the accompanying engravings. Each chamber is divided by an apron into two parts, and the openings connecting two chambers on alternating sides of the partition-walls commence a considerable distance above the floor, so that the current has to change its direction several times in passing from chamber to chamber, while the dust collected at the bottom remains undisturbed, and can accumulate in considerable quantities before discharging becomes necessary. I will mention here, that in roasting ores with salt, the dust which has been chloridized by passing the flame of an auxiliary fire-place connected with the flue of a roasting-furnace settles much easier than dust which has not undergone this treatment, or has been roasted, merely oxidizing. The reason is easily found. Red-hot ore, roasted with salt, is sticky, and clings whenever it is thrown by the current of gases against a solid surface. Hence, frequent changes in the direction of the current bring the particles into contact with the dust-chamber walls. What is effected at Ems by a maximum of surface, I effect by frequent changes in the direction of the current. Both constructions have their especial application, and whenever dust and fumes from smelting-works are to be collected, the Ems construction is, no doubt, the best. For dust-chambers close to a roasting-furnace, which produces a very large quantity of dust, my construction is preferable on account of working facilities. The first dust-chambers of a Stetefeldt furnace get exceedingly hot, being close to the auxiliary fire-place, and sheet-iron suspended therein would warp, and be destroyed by the acid fumes at such a high temperature. But both systems can be combined with profit in this case, utilizing the Ems construction in the last chambers, and in the flue leading from there to the chimney. How well these dust-chambers operate, the following statistics will show, which are the results of experiments carried out at the Ontario mill with Stetefeldt furnace No. 2. The ore roasted at the time was exceedingly base, and a strong draught was needed to supply sufficient air for oxidation, so that by far the largest portion of the ore was floated out of the shaft and into the flue, thus putting the settling capacity of the dust-chambers to a severe test.

The experiment was carried out in the following manner: All the roasted ore was discharged into iron cars of equal size, and care was taken to fill them uniformly. An accurate record was kept of the number of cars which were discharged—

1. From the shaft.
2. From the flue below the auxiliary fire-place.
3. From the first six dust-chambers.
4. From the last six dust-chambers.

Samples were taken from each car, and the average samples sealed up in glass bottles, to prevent the roasted ore from attracting moisture. In these samples was determined—

1. The value in silver.
2. The percentage of soluble salts
3. The value of the roasted ore after leaching out the soluble salts.
4. The weight of equal volumes, so that relative weights could be calculated from relative volumes. The experiment was continued for ten days. As a check for the accuracy of the work, samples were also taken from the cars transporting the roasted ore to the pans, after it had been cooled and thoroughly mixed on the cooling-floor. The value, solubility, etc., of these samples agreed very closely with the calculated average values of the four sets of samples to which reference is made above, showing that the accounts kept by the furnace-men were correct. The value of the raw ore was $156.15; the percentage of salt used in roasting, 18·4 per cent.

TABULATED STATEMENT, SHOWING RESULTS OF EXPERIMENTS.

Average from ten Samples.	Roasted Ore discharged from:			
	Shaft.	Flue below aux. fire.	First six dust-cham.	Last six dust-cham.
Value in silver.	$114.44	$122.36	$122.55	$102.88
Soluble salts, per cent	24.7	25.9	33.2	37 1
Value after leaching...	$153.23	$164.95	$182.89	$163.93
Weight of equal volumes, calling weight of ore from shaft 100	100	88	70	59
Calling value of raw ore 100, the value of roasted ore after leaching is.....	98	106	117	105

Calling total weight of roasted ore 1000, we find in.....	317	561	112	10
Calling total weight of roasted ore, after leaching, 1000, we find in	325	566	101	8
Calling total amount of silver in roasted ore 1000, we find in.....	1:06	571	114	9

THE SWEDISH IRON INDUSTRY.

From the official returns just published for the period 1881–82, great progress appears to have been made in the iron and coal trades of Sweden.

The winter 1881–82—winter being the season when most work is done in the Swedish furnaces—was an unusually mild one, and the quantity of charcoal brought out from the forests, in consequence, comparatively small. It is a remarkable circumstance that in this country the larger iron deposits, which in some places extend more or less continuously for from fifty to a hundred miles, are entirely denuded of those species of trees from which charcoal may advantageously be made. The consequence of this is, that iron mines are found where there is no charcoal, while charcoal is plentiful in districts where there is no iron ore; and for this reason the wood fuel—and this is the only kind used in Sweden—has to be brought to the furnaces long distances, from places where there are generally no railroads, on sleighs in the winter, when snow and ice cover the country and its water-courses. Although a severe winter is indispensable to a great manufacture by the works, the numerous railroads lately built, partly by the state, but chiefly by private individuals, have during recent years to a great extent made the Swedish iron-master independent of climatic conditions, and the time is doubtless not far distant when easy and cheap means of communication will bring the extensive forests of which the country can boast within easy reach of the iron-works, and the two most important factors in the industry into complete co-operation.

In the spring of 1882, very high prices for iron and steel were anticipated in Sweden, chiefly in consequence of the alleged scarcity of charcoal, which would, it was asserted, curtail the make; but these anticipations were not realized, and this tends further to corroborate the above statement, that the Swedish iron-master is far more able to obtain his supply of fuel at the present day than ten years ago. The two kinds of iron now chiefly made in Sweden are pig and bar-iron, and although the former was in years gone by the chief metal produced in Sweden, the price has gradually gone down. Although it is still made in large quantities by furnaces which are without the modern appliances for the new processes, its export has diminished year by year in proportion to the increase in make. And while the English market was formerly the best for makers of pig-iron, the demand has of late gradually decreased, and the prices have in consequence been very low. This circumstance is, however, not due to any deterioration in the quality of Swedish pig-iron, but to the fact that English foundry pig, which seems to answer the purpose, may be offered at half its price in England, and even exported into Sweden under the cost of common gray Swedish pig. With respect to this kind of iron, little improvement may be expected, as the Swedish manufacturer has not at present the capital necessary to adopt the

Digitized by Google

modern processes, which, at a lower cost, produce a metal relatively better, or, at all events, perfectly answering the demands put upon it.

In 1880, there were 193 furnaces making pig-iron in blast in Sweden, turning out a total of 399,500 tons of pig-iron, and 4500 tons of castings directly from the furnace. In 1881, there were 197 furnaces in blast, turning out a total of 416,700 tons of pig-iron, and 5280 tons of castings directly. This is an excess, therefore, in 1881 over 1880 of 17,200 tons, while the average output per furnace in 1881 was 2110 tons, against 2050 tons in 1880. The greatest quantity made in 1881 by one concern was 10,000 tons at the Hofors Iron-Works, where there are two furnaces; and the smallest, 132 tons, by a furnace in the province of Calmar.

If we turn to the latest statistics of the malleable iron industry for 1881, we find that there were 276 works for its manufacture in operation, with 745 hearths, of which four were puddle and three Martin furnaces, making a total of 253,600 tons; while in 1880 there were 270 works in operation, with 731 hearths, of which six were puddle and four Martin furnaces, making a total of 217,300 tons of such iron. The excess in 1881 over 1880 was, therefore, 36,300 tons, while the average return per rolling-mill in 1881 was 920 tons, against 805 in 1880. There were also made during the year 134,000 tons of blooms, against 130,000 tons in the previous year, which had been rolled or drawn into bars at rolling-mills attached to other kind of works.

The manufacture of pig and bar-iron, with castings, during the quinquennial period has been as follows:

	1877. Tons.	1878. Tons.	1879. Tons.	1880. Tons.	1881. Tons.
Pig-iron	335,000	327,000	330,000	399,500	404,300
Bar-iron	222,200	194,000	205,000	217,300	253,600
Castings directly from the foundry	8,470	8,250	6,020	4,500	5,220
Castings by re-smelting pig-iron	18,300	13,200	10,600	12,540	13,530

From these statistics, it will be seen that the production of pig and bar-iron has gradually increased during the last few years, while the making of castings has decreased. There is, however, perhaps no industry which can show such remarkable results as the steel industry of the country during the last few years, which is no doubt owing to the large construction of steel steamers in recent years. Sweden seems thus to be the ship-building mart of the neighboring countries, and last year there was launched a larger number of vessels than in any previous year. The chief customer for these appears to be Russia, in spite of the duty there on all vessels built abroad. The Swedish yards have contracts on hand to last for the present year. Orders from some countries have been declined, while the activity at the works is strained to the utmost. In connection herewith, it should be mentioned that the first contract for the building of a war vessel by a private firm in Sweden, has just been given by the government to the Kockum works, at Malmö, namely, the construction of the iron corvette Freia.

During 1881, there were thirty works manufacturing steel in the country, making a total of all kinds of 48,678 tons, and the following table shows the detailed production of the important metal in the various provinces (län), with the number of works in each. The term Bessemer steel covers all steel manufactured on this principle, irrespective of hardness.

Name of County (Län).	No. of works.	Bessemer steel. Tons.	Martin steel. Tons.	Other kinds. Tons.	Total. Tons.
Vesternorrland	1	.....	.....	5	5
Gefleborg	3	12,115	.....	.....	12,115
Upsala	2	.....	.....	313	313
Kopparberg	4	6,983	1,921	87	8,991
Vestmanland	3	3,224	.....	723	3,947
Orebro	4	6,600	957	17	7,574
Vermland	10	9,636	5,533	220	15,389
Elfsborg	2	.....	.....	343	343
Ostergötland	1	.....	.....	1	1
	30	38,558	8,411	1,709	48,678

Among "other kinds," are some blister, cast, and puddle steel. Bessemer steel was manufactured by the following works: Iggesund, 2973 tons; Sandviken, 7700 tons; Forsbacka, 1450 tons; Domnarfoet, 2975 tons; Langshyttan, 3130 tons; Ulfshyttan, 834 tons; Vestanfors, 3230 tons; Bangbro, 5450 tons; Stjernfors, 1140 tons; Uddeholms Works, 2845 tons; Borgvikshyttan, 504 tons; and Björneborgsshyttan, 2062 tons; total, 38,558 tons. In 1880, there were also thirty steel-works in operation in Sweden; but as these in 1880 returned 36,730 tons of steel, there is an increase in the outturn of very nearly 12,000 tons, which figure speaks volumes for the progress of this industry, particularly as 9122 tons are Bessemer steel alone. The manufacture of steel has advanced during the quinquennial period as follows: 1877, 24,300 tons; 1878, 25,400 tons; 1879, 27,101 tons; 1880, 36,730 tons; 1881, 48,678 tons; and has thus been nearly doubled in five years. One of the principal features of the Swedish steel manufacture is the successful attempt which has recently been made at Bofors to manufacture steel guns from Martin steel on the Terre-Noire method.

Several attempts have also been made to make guns by the Bessemer process; but as these have been unsuccessful, they have been abandoned. The guns are cast at Bofors in molds giving them almost their final shape, and are not subjected to any other treatment before being finished than reheating and hardening, by which their cost is less than if made from other kinds of steel which require forging. Up to the present, ten guns have been cast at Bofors from Martin steel, six of which have been tested, one is under finish, and three are still in the crude form. The testing of four of these guns, which was made in order to try their strength only, was effected with 1060 firings of one, and 2000 firings of the three others, which were then burst under an atmospheric pressure of 5000. The excellent quality of the steel was fully demonstrated. Thus, even after 2000 firings, the guns were just as uninjured as before the trial, and when bursting, the steel showed an elastic limit, which was remarkable even for this kind of steel. The bursting itself showed that the steel was without defect or flaw, while it had stood the test equally well in all parts, even where the strain was greatest, to which, perhaps, the shape of the guns—exactly similar to the Krupp field-pieces—contributes somewhat. In future, the Swedish government contemplates having all the guns required by the artillery made at Bofors of Martin steel, which it is now at liberty to do, the contract between it and Messrs. Krupp having expired this year. For the ensuing year, the government has ordered from Bofors several batteries of field-guns, to be made from hardened Martin steel; and if this new industry should prove to answer, there is every probability of the government having also the guns of the navy made in Sweden. Besides guns, these works delivered last year to the army some thousand rifle-barrels of close forged Martin steel, as well as material of the same metal.

With regard to the finished iron and steel industry of the country, there is considerable progress to record during the last few years. Still, Sweden imports yearly a far larger quantity of such articles than she exports. In 1881, there were 159 works in operation in the country, which turned out 37,500 tons of all kinds of manufactured articles; in 1880, there were 177 such works in operation, turning out 32,500 tons, which is therefore an increase of 5000 tons, although the decrease in the number of works was 18. In 1881, there were made 12,875 tons of plates, 12,600 tons in 1880; 6978 tons of nails, 7300 tons in 1880; 1380 tons of tools and implements, 1400 tons in 1880; and about 16,000 tons "sundry manufactured articles," against 11,400 tons in 1880, under which heading the increase has therefore chiefly taken place. Among these were 2900 tons of machinery, railroad tires and axles of Bessemer metal, 1000 tons of iron and steel wire, 200 tons of chain cables, etc. In 1881, there were employed 6286 workmen at these 159 works, against 5850 in 177 works in 1880. During the quinquennial period, the quantities of manufactured goods were as follows: 1877, 38,500 tons; 1878, 36,100 tons; 1879, 27,500 tons; 1880, 32,500 tons; 1881, 37,500 tons. Last year, there was started a manufactory in Sweden for horseshoe nails by an American firm, which is the only one of its kind in the country. Horseshoe nails have previously been made in Sweden, but only by "clipping." With the modern machinery at the American works, they are, however, forged, which increases their value nearly fifty per cent. The nail hammers at these works are twelve, driven by an engine of 27 horse-power, turning out 10,000 nails a day, while every nail receives from 80 to 90 strokes.

The iron ore production of Sweden has risen considerably during the last few years, and we shall have to go back to the year 1873-74—the most flourishing on record—to find figures which compare with those of 1881. In 1881, ore was raised in thirteen of the twenty-four provinces of Sweden, with a total of 806,000 tons, which is an increase on the previous year of about 50,000 tons. As regards the quantity of ore broken out, Sweden ranks after England, France, and Germany, but before Belgium, Russia, Austria, and Spain. The greatest quantity was raised in the province of Orebro, whose 262 mines produced 220,000 tons; next comes Kopparberg, with 181 mines, 210,000 tons. But Vestmanland shows the greatest concentrated output, as 170,000 tons were raised from fifty-seven mines.

But here are also situated some of the richest deposits in Sweden—Risbergsfältet, whose seven mines alone give nearly 50,000 tons, Klacksbergsfältet, and Morberget. In the provinces of Jönköping and Kronoberg, there were also in the year 1881 raised about 5000 tons of lake or bog ore. During the quinquennial period, the output of "mountain" ore was as follows: 1877, 772,000 tons; 1878, 600,000 tons; 1879, 630,500 tons; 1880, 755,000 tons; 1881, 806,000 tons. If we turn from these statistics of the iron and steel industry to those of trade, we shall find that the latter has during the last few years made as enormous strides as the former. During the last three years, the exports of Sweden were as follows:

	1880. Tons.	1881. Tons.	1882. Tons.
Pig-iron	61,519	55,290	55,500
Bar-iron, rolled or forged	131,220	136,556	154,000
Iron plates, hoops, etc.	50,000	52,000	56,000
Blooms	8,860	8,802	8,000
Rails with bolts, etc.	.....	2	30
Plates, galvanized and otherwise	2,174	2,362	2,200
Nails, 1-6-inch and above	876	1,052	900
Steel, in ingots	8,155	7,165	9,800
Iron ore	29,662	24,232	20,200
	292,466	287,461	306,630

From these figures, it will be seen that the articles which form the staple of export have greatly increased, while the decrease in the export of plates and iron ore bespeaks an increased consumption at home. From the figures we have just given of the exports of 1882, it may be safely concluded that that year will also, as regards the manufacture, show an advance on those of the previous years. As regards the import of iron and steel, the figures for 1881 show an advance on those of 1880, while those of 1882 will no doubt exceed them both. Of steel and iron rails, there were imported from England, in 1882, of steel 6952 tons, of iron 2435 tons, as against 4416 tons and 2222 tons respectively in 1881.

FURNACE, MILL, AND FACTORY.

The Ward Iron Company at Niles, O., has failed.

The Atkinson Diamond Drill Company has sunk a well 475 feet deep at Stapleton, Staten Island, N. Y., for a brewery.

A new machine for perforating all sizes of metal has lately been put in place by Harrington & King, of Chicago, and is working very satisfactorily.

The Dover *Iron Era* reports on the 21st that one hundred and one tons of iron were made in the twenty-four hours ended on Friday morning last, at the Durham Iron-Works, in a single stack.

A new barb fence wire company is to be located at Ottawa, Ill., on the lines of the Chicago, Burlington & Quincy and Chicago & Rock Island railroads. The capital has been subscribed, and the company will begin operations within the next ninety days.

The Stover Manufacturing Company, of Freeport, Ill., manufacturers of special machinery, have completed fifteen barb-wire machines for the H. B. Scutt Company, of Pittsburg.

The beam of the new high-service engine of the St. Louis Water-Works is 84 feet long, 7 feet deep in the center, is composed of wrought and cast-iron, and weighs 68,000 pounds. The pump casting proper weighs 84,000 pounds, the cylinder and jacket weigh 28,000 pounds, the lower and upper head of the cylinder 16,000 pounds, the air-chamber 66,000 pounds, the columns supporting the beam 56,000 pounds, the bed-plates 64,000 pounds, and the pump-plunger and bucket 20,000 pounds. The piston is 85½ inches and the piston-rod 8½ inches in diameter, with 10-foot stroke. The engine is to be run by six boilers 24 feet long, of the pattern known as the drop-flue return boiler. A temporary frame build-

Digitized by Google

ing is erecting over the new engine. The foundations connected with the engine have been constructed to accommodate three more engines, and the plan is to place the engines in position before erecting the engine-house. The foundation of the new boiler-house is designed to accommodate twenty-four boilers, which will generate the steam to run the four new high-service engines.

Mr. H. H. Porter has issued a circular containing the following plan for reorganizing the Union Iron and Steel Company of Chicago: A new company is to be formed to buy out the whole property of the present company. The capital stock of the new company to consist of a seven per cent cumulative

Preferred stock of	$3,000,000
And a common stock of	1,600,000
Total	$4,600,000

The preferred stock to be used in paying the indebtedness of the company at par as follows:

First mortgage bonds	$500,000.00
Second mortgage bonds	684,000.00
Bills payable	1,484,389.07
Accounts payable	152,877.89
Total	$2,821,266.96

If the second mortgage bondholders (and holders of more than one half have already expressed their willingness to do so) will take preferred stock at par for their bonds, and the holders of the bills and accounts payable will take preferred stock at par for their notes and claims, the representatives of the "Stone" indebtedness (which is included in the figures given above) will buy the first mortgage bonds at par and will take preferred stock for them.

The whole plan is conditioned on all the creditors assenting to it by August 1st next. On giving said assent, so as to insure the carrying out of the plan, they will, on notice, be expected to deposit the evidence of the indebtedness due them in the hands of some proper trust company for that purpose.

The condition of the new company on this basis would be:

Preferred stock (which would be used in paying the creditors as shown above, any surplus to remain in the treasury of the company for its future disposition)	$3,000,000
Common stock (which would be used in exchange, at par, for the stock of the present company to same amount)	1,600,000

And this new corporation would represent and own:

A. The Union Iron and Steel Company's plant at Chicago.

B. The Union Iron mine on the Menominee range, subject to its royalty contract of 50 cents per ton.

C. About 5700 acres of land on the Menominee iron range (Michigan).

D. Interest in patent of Bessemer Steel Company (Limited).

E. Cash and working supplies to run the steel-works, of a value of from $675,000 to $750,000.

F. Any surplus of preferred stock not required in paying the indebtedness.

G. Some doubtful accounts on which investigation indicates that $100,000 at least should be collected.

I estimate the fair cash value of all the personal property of the company, if used in running the works, to be from $850,000 to $1,000,000, in addition to the plant itself.

It seems to me that this plan is a feasible and practicable one, and is probably the most profitable way of reorganizing the company in the interest of the creditors. An industry of this kind, in the hands of a receiver, is necessarily expensive, unsatisfactory, and injurious to the company, and consequently to the creditors.

If all the creditors will assent to it, I will attempt the reorganization of the company on this basis; and if any of them shall prefer to take 50 cents on the dollar in cash for their indebtedness, instead of preferred stock, I believe I can find parties willing to buy their claims, and take their places in carrying out this reorganization scheme.

Accompanying this is an inventory setting forth the property of the company as presented to the court by the receiver, including the mills, docks, steel-works, furnaces, mining lands, etc., which amount to $2,901,759.37. The circular is also accompanied by a proposition in blank for the signature of the stockholders.

On the morning of the 20th, a fire was discovered in the timbers over the main battery of boilers at Everson, Macrum & Co.'s mill. Second avenue and Monongahela River, Pittsburg. There was a turn at work, the third heat being in the guide, bar, and sheet-furnaces; but the flames spread so rapidly that the employés were driven pell-mell from their work. The boiler-house is located on made ground on the river-bank, parallel with the main mill building, both being iron-clad and iron-roofed. The fire having reached the main building, and made such headway as threatened the entire destruction of the structure, the boiler-house was destroyed, and with it the stack and breeching. The boilers were not damaged. One half the mill building was burned or so much damaged as to require this portion to be rebuilt. The machinery, consisting of three large engines, four trains of rolls, shears, etc., was not damaged. Heats were in the guide, bar, and small sheet-furnaces, and these cooling off will cost something to clear out, although, as the furnaces are sand bottoms, the damage to them will amount to little. The guide mill furnace is the only one that will need material repairs, the stack being in a tottering condition. The loss will not exceed $10,000.

A train going at full speed jumped the track and ran into the works of the East Tennessee Zinc Company, at Knoxville, Tenn., tearing away the whole side of the building and playing havoc with the machinery. The locomotive engine ran into the stationary engine of the Zinc Company, demolishing the latter completely. The damage to the railroad company is about $10,000, and to the Zinc Company $6000. The accident was caused by a misplaced switch.

A contract has been signed by M. C. Bullock, President of the Diamond Drill Manufacturing Company, of Chicago, and citizens at Rich Hill, Mo., to have a hole bored with a diamond drill to the depth of 1000 feet in the vicinity of Rich Hill. The drill will bring out a core about two inches in diameter.

An accident occurred on the 23d at the Onondaga Iron Company's blast-furnace, about half a mile west of the village of Geddes, N. Y. For several weeks, the blast-furnace has been out for repairs. Men have been engaged for several days in removing the fire-bricks of the arch, leaving only the outer course standing. At thirty-five minutes past three o'clock, a gang of eight men was lining the blast-furnace, which is 16-foot bosh and 60 feet high. The men were relaying the bricks on the lower part, and a small scaffold was laid across the furnace eight feet from the ground. Without warning, the lining of the upper part suddenly gave way, and sixty tons of brick fell upon the men. An alarm was at once given, and the workmen at the mill set to work with a will to remove the victims. In less than an hour, the bodies of the eight men were taken from the ruins. The manager claims that the men were warned.

The Cincinnati *Enquirer* says that the managers of the Kentucky Union Company have closed a trade for the Kentucky River Iron-Works property, in Estill County, paying about $500,000 for it. This makes the third piece of valuable manufacturing property bought in that section by the Kentucky Union Company.

The contract has been let and the ground broken for the new pattern-shop of the Dickson Manufacturing Company, Scranton, Pa. This establishment is fast becoming one of the largest of the kind in the United States.

The Dean Brothers steam-pump works, of Indianapolis, have just shipped two large double plunger mining pumps to coal mines in Alabama.

MINERAL PATENTS GRANTED BY THE UNITED STATES LAND-OFFICE.

The following mineral patents were promulgated by the General Land-Office during the week ended Saturday the 21st of July:

ARIZONA.

TUCSON DISTRICT.

Solomon Warner, Santa Tomas lode. Horseshoe Mining Company, Alta lode.

CALIFORNIA.

MARYSVILLE DISTRICT.

Henry Downing, Evening Star placer. Norman A. Harris, Lucky Strike placer. J. M. Ward, placer.

SACRAMENTO DISTRICT.

Cyrus T. Wheeler, Wildman quartz mine.

COLORADO.

CENTRAL CITY DISTRICT.

Bullion Tunnel Company, Hamer No. 1 lode and mill-site. Charles C. Emigh, Red Bird lode. Mary G. Peck *et al.*, Gold Dirt lode. Nathan S. Hurd, Creole lode. Robert M. Richardson *et al.*, Pickwick and My Daisy lodes. Lebanon Mining Company of New York, Champion lode and mill-site. William Dillon, Dillon lode. Annie R. Sprenger *et al.*, Edinburgh lode. Benjamin T. Wells, Seven Twenty lode. Peter D. Graham, Graham lode. Consolidated Bobtail Gold Mining Company, Warwick lode.

DURANGO DISTRICT.

Angus Smith *et al.*, Cross, Pittsburg, and Hope lodes. E. P. Suydam, Rico Muldoon lode. Cleveland Consolidated Mining Company of Colorado, Little Bertha lode. E. J. Warner, Boston placer. Dinant du Ponte, Iron Clad lode. Thomas Blair, placer.

LAKE CITY DISTRICT.

David A. McConnell, General Sherman lode. Dolobran Mining Company Pioneer lode and Revenue and Union lodes and mill-sites. Joseph Donnell *et al.* Alps lode. W. Weston *et al.*, Finance lode. Hugh J. Alexander *et al.*, Yellow Jacket lode. Old Reliable Mining and Reducing Company, Little Fraud lode. C. Patz *et al.*, Governor Pitkin lode. Dennis Kenyon *et al.*, Jim Fisk lode. Summit Mining Company, Summit lode.

LEADVILLE DISTRICT.

Samuel Cohen, Grand Prize lode. J. P. Whitney, Milton Belle, Dexter, and Pete Carroll lodes. Thomas Carney *et al.*, Iron and Cavern lodes. Stray Horse Gulch Mining Company, Rarus lode. John A. Smith *et al.*, Fox and Rattlesnake lodes. Elisha A. Buck, Rustler lode. Aaron K. Styles, Paducah lode. Park County Silver Mining Company, Black Hawk lode. Berlin Mining Company, Frisbie placer mine. Excelsior Consolidated Gold and Silver Mining Company, Little Hattie lode. Warrior's Mark Mining Company, Ætna, Warrior's Mark, Queer Name No. 1, Queer Name No. 2, Cassandra No. 1, Cassandra No. 2, Cassandra No. 3, Cassandra No. 4, Cassandra No. 5, and Warrior's Mark No. 2 lodes. Thomas S. Wells, placer. W. Z. Ransom *et al.*, placer. Alleghany Mining, Smelting, Tunneling, and Milling Company, placer. George M. Robison *et al.*, Laura lode. Charles F. Reynolds *et al.*, Main lode. B. B. Hugus *et al.*, Alpha, Beta, and Maverick lodes.

PUEBLO DISTRICT.

W. J. Schoolfield *et al.*, Rappahannock lode.

IDAHO.

BOISE CITY DISTRICT.

Robert C. Chambers, Iris lode. Vienna Consolidated Mining Company, Alturas lode.

MONTANA.

HELENA DISTRICT.

William A. Clark, Missing Link lode. Daniel B. Noble, company lodes and mill-sites. James Thompson *et al.*, Golden Gate lode. Edward King, placer.

NEVADA.

CARSON CITY DISTRICT.

J. H. McNee, Garfield and Arthur salt and borax placers.

EUREKA DISTRICT.

Madeline Goetz *et al.*, Star of the West lode.

NEW MEXICO.

LAS CRUCES DISTRICT,

Patrick Dorsey, Kelly lode. Thomas F. Conway *et al.*, Ivanhoe lode.

UTAH.

SALT LAKE CITY DISTRICT.

Sylvester T. Everett, Chloride Gem and Jim Fisk, Jr., lodes. James McTenny and S. T. Everett, Green-Eyed Monster lode. Romeo Consolidated Mining Company, Romeo lode. James Robbins, Senior, Robbins Eureka lode. Robert C. Chambers *et al.*, Central lode and Washington mill-site. William S. Searls *et al.*, Day Dawn lode. Samuel W. Smith *et al.*, Cornucopia ledge and company lode.

WYOMING.

EVANSTON DISTRICT.

Samuel E. Rogers, oil placers.

GENERAL MINING NEWS.

ARIZONA.

GLOBE DISTRICT.

OLD DOMINION.—Shipments for this week are 335 bars—106,155 pounds. Total to date, 3,694,430 pounds. One furnace will be started on Monday, and a second one as soon as coke accumulates.

GRAHAM COUNTY.

DETROIT.—The Clifton *Clarion* reports that the Detroit Copper Mining Company is making preparations to do business on a large scale. The hoisting-engine on Copper Mountain is nearly ready to start up. The engine-house is completed, and presents a very neat appearance. A winze has been started from level No. 3, and is going down in first-class ore. The stopes all through this mine are looking well, and are producing more ore than at any time previous.

TOMBSTONE DISTRICT.

CONTENTION.—About sixty miners have been laid off. This reduction of the working force is only temporary, and was necessitated by the putting in of the pumping machinery, which will be commenced at once.

CALIFORNIA.

THE BODIE DISTRICT.

VIRGINIA CREEK HYDRAULIC.—The *Free Press* says: Bar No. 1 of the Virginia Creek Hydraulic Mining Company has been melted by A. Soderling, the assayer, giving a value of $2000. This company is operating at the old Mono diggings, and but a few days since began hydraulicking with a little giant. There is an ample supply of water.

BODIE CONSOLIDATED.—The official report for the week ended July 13th shows: Ore crushed, 131¾ tons; average assay value of pulp, $20.33 per ton;

Digitized by Google

of tailings, $4.54. Bullion shipped, $3122.18. The west cross-cut, 1000 level, is 297 feet long. North drift, same level, is 315 feet long. The east cross-cut, 1000 level, is in 382 feet. The south drift from bottom of winze No. 2 is in 25 feet. The south drift from winze No. 6, at 640 level, is 197 feet long, and uprise No. 23 from 672 level is up 65 feet.

STANDARD CONSOLIDATED.—The official report for the week ended July 14th shows: Ore extracted and shipped to mills, 1494 tons; bullion shipped, $22,307.65. The east cross-cut, 1200 level, is 378 feet long. The north drift No. 1, 1000 level, is in 229 feet, and shows the vein 1½ feet wide. The south drift No. 3 is 178 feet long; the vein is 5 feet wide and looks well. Uprise No. 1 from this drift has reached the hight of 70 feet, where the vein is 4 feet wide. The west cross-cut from north drift, 700 level, is 348 feet long, and is in hard ground. The south drift from the west cross-cut No. 1 is in 174 feet, and shows the vein 3 feet wide. The south drift No. 2, 385 level, is in 665 feet; vein, 4 feet wide. The north drift No. 2 is 262 feet long, and shows 8 feet of vein. The uprise from south drift No. 2 is up 234 feet, and the uprise from the north drift No. 1 is up 200 feet. The stopes show no change.

SAN BERNARDINO COUNTY.

The *Calico Print* of July 7th has this to say of the mines along the Atlantic & Pacific division of the Southern Pacific Railroad: The Silver King shows up richer as it goes down. The average milling returns of its ore are now a little over $100 to the ton. The Garfield, which is down about 130 feet, has doubled in value within the last week. William Raymond, the owner of this fine mine, has made arrangements to have his quartz mill shipped from Nevada, and in two or three months it will be erected and in operation at the Fish Ponds. The ore taken out from the big copper mines in Ord District will soon be passing through a smelter which Osborn & Co. will put up in a few months. The mill for the Alvord gold mine is bought and active operations are beginning on this rich mine, and it will not be long before one hundred stamps will be reducing its ore. The gold mines at Paradise Valley will also be opened up as soon as the hot weather is over. The Lava Beds, which are beginning to attract so much attention on account of their rich showings, will be the scene of lively times this fall. A town will be laid out and a dozen or more good mines will be employing a large number of men, who will support a good-sized town. The owners of the mines bought from the Clark Brothers for $20,000 will shortly put up a mill, and a branch railroad will be built to the mines, which will be but the commencement of extensive operations. The above enterprises, in connection with the constant operation of the Pioneer, Oriental, Waterman, and Oro Grande quartz mills, will create a large amount of business and traffic in this section of the country.

COLORADO.

BOULDER COUNTY.

GOLDEN STAR.—John Ritchie, of Gold Cliff, the owner of this property, is negotiating for the erection of a concentrator.

NORTH PLATTE MILLING AND MINING COMPANY.—This company has just started up with its new plant of two sets of steam stamps and Rouse concentrating-tables at Gold Hill. The old stamp-battery has been abandoned and replaced by the Sharpneck steam stamp, of which there are two in each battery, having a daily capacity of from 15 to 18 tons. These are run at a rate of 175 drops per minute, although the stamps have an actual capacity of 300 drops per minute, worked on the plan of a steam-hammer. There is no contact of shoe and die when there is no mineral between them, the impact and consequent wear and tear being prevented by a steam-cushion. The stamps take steam directly from the boiler. From the stamps, the pulp passes to an automatic sorter, then to two sets of Rouse concentrating-tables, which have been steadily at work for over a year, making a saving of over 80 per cent on the tellurium ores from the Prussian mine, with the owners of which there is a contract for working 10,000 tons, after which the mill will be ready for general custom work.

CHAFFEE COUNTY.

The new concentrating-works of P. J. Cunningham & Co., at Windfield, will be started up soon.

DOLORES COUNTY.

Under date of the 20th, Mr. Linwood O. Towne sends us the following notes:

ELLA D.—This claim adjoins the South Park, its owners having been sinking a shaft to cut the vein of the latter, which is horizontal. This was effected to-day at a depth of 70 feet, where the same bituminous shale, silver-bearing, was struck. This finding of the South Park vein on adjacent property has occasioned considerable excitement, and shafts will at once be sunk on other claims in the vicinity.

GRAND VIEW.—Mr. H. O. Hofman, of Philadelphia, has just assumed charge as metallurgist, and smelting under him is proceeding with satisfaction. Since the recent shutting down of the furnaces, ore has been constantly bought and important changes made about the works. An additional blower has been put in, and a new engine, which has also been added, will be used for blowers alone, thus insuring uninterrupted blast.

SANTA CLARA REDUCTION-WORKS.—The works are running constantly, making regular shipments of fine gold and silver bullion.

SOUTH PARK.—This property, which has so suddenly come into prominence, continues producing large quantities of high-grade ore, shipments being made to the Rica reduction-works and Grand View smelter. The character of the ore, which is one of the most eccentric ever found in the State, remains practically the same. It is almost a fire-clay in general composition, but nearly black in color through bituminous matter, which is easily burnt off. Shipments to the smelter run from 100 to 350 ounces of silver per ton. It is quite impossible to sort the ore, specimens of which will assay up in the thousands. The silver occurs native and as a sulphide in sulphate of lead.

FREMONT COUNTY.

A correspondent of the Denver *Republican* says, writing from Rosita: While prospecting for a saw-mill site a few days since, close to the line of the Denver & Rio Grande Railroad, and not far from what is known as Cedar Ridge, and about on the line of Custer County, I came on a half-dozen miners working a claim known as the Newsboy, and piling up ore by the ton from a four-foot vein of rich galena. It runs 16½ ounces in silver and from 60 to 66 per cent lead and some copper. The owners are Thomas McEwing, now superintendent of the Julianna, and Hon. Frank Hunter, discoverer of the famous Johnny Bull mine.

GUNNISON COUNTY.

GUNNISON MINING AND MILLING COMPANY.—It is reported that R. D. Smith, of Pekin, Ill., proposes to remodel the concentrator.

LAKE COUNTY.

The erection of a third furnace at the Elgin smelter is under advisement.

The fourth furnace at the American and the fifth furnace at the Arkansas Valley smelter have been blown in.

There is now not an idle smelting-furnace in Leadville. The list of reduction-works is as follows: Cummings & Finn, five furnaces; Elgin, two; Harrison, four; La Plata, five; American, four; Arkansas Valley, five.

MORNING STAR.—A large body of ore in the Morning and Evening Star mines has been opened, which runs 50 ounces in silver and between 40 and 50 per cent lead. It was thought that this ore would not run higher than 20 ounces in silver.

ROBERT E. LEE.—The Carbonate *Chronicle* says: The workings of the Robert E. Lee remain a mystery. The pending sale is expected to be consummated by the latter part of the present month at the farthest. Prospecting has been kept up since the shut-down, and various conflicting reports are current as to the either the new discoveries. That there have been some very valuable deposits value of up there is no doubt, but nothing authentic will be given the public until opened the sale is made to the English syndicate or declared off.

SILVER CORD.—At a quarter-past five Sunday morning, the explosion of a lamp in the boiler-room of the Silver Cord Mining Combination's buildings spread oil and flames in every direction, resulting in the destruction, in less than an hour, of probably $40,000 worth of property. The machinery building was 90 by 40 feet, covered by an iron roof, and contained in the southern end the large one hundred horse-power hoisting-engines, with two drums, and was acknowledged the finest rig of the kind in the State. Next to the engine-room were the compartments containing the miscellaneous machinery, and adjoining it the boilers, three in number. In the former room was a No. 5 air-compressor, a thirty-five horse-power engine for the saw-mill, a twelve horse-power Westinghouse engine, and a twelve-light dynamo machine. Adjoining this was a fully-equipped machine-shop, and beyond it the saw-mill and carpenter-shop, with wood-lathe, saw-gummer, and other appurtenances. The building and its contents were valued at $40,000, and were covered by insurance to the extent of $19,700, of which amount $16,400 were on machinery and $3300 on buildings, including also $500 on the ore-house. The ore-house contained a sorting-floor 80 by 13 feet, and twelve ore-bins, which had a capacity of about eight hundred tons. The fire entailed a loss of time in working the mine of but three hours, as temporary hoisting-engines were immediately set up, and at ten o'clock the mine was again hoisting ore.

SAN JUAN COUNTY.

BEN FRANKLIN.—This mine, recently opened in Eureka Gulch, and owned by Webb & Whilton, has opened out very well.

NORTH STAR.—This property, owned by the North Star Company, has been sold to L. B. Kendal & Co., of Kalamazoo, Mich.

SILVER WAVE.—The owners of this property on Mount Bross have struck good ore.

WESTON CONSOLIDATED.—The Hock, Hocking, and Weston mines, belonging to the Weston Consolidated Mining and Milling Company, have been leased for three years to Messrs. Neftel, Churchill, and Parks, of New York. These gentlemen propose to put in a large amount of machinery, and, as soon as the water can be taken from the mines, to work the whole property to its fullest capacity.

YANKEE GIRL.—This mine is working twenty-two men. The tunnel is in 170 feet, to the bottom of No. 2 shaft, which is 75 feet deep. Shaft No. 1 is 50 feet deep, to where the tunnel cuts the same. From this level, the shaft is down 60 feet, all through solid ore. The shaft is 10 by 14 feet. For the last few feet in this shaft, the ore on the foot-wall is gray copper of high grade. This shaft will be tapped by a cross-cut from the Orphan Boy tunnel, some twenty-five feet in length, when the present output will be doubled and the mine put in much better shape for working. Very little dead-work has been done on this property heretofore, but the company is now fitting up for permanent work. A new boarding-house, 20 by 50, two stories, capable of accommodating seventy-five men, is nearly completed. An ore-house and blacksmith-shop will be constructed at mouth of the Orphan Boy tunnel for the accommodation of both mines. The present output of the Yankee Girl is 20 tons per day, and runs in large lots, from 140 to 150 ounces of silver and 40 per cent lead.

SAN JUAN REGION.

H. A. W. TABOR.—Mr. R. R. Russell has sold to Eaton, Smith & Co., of Gunnison, the H. A. W. Tabor lode, which is situated on the mountain northeast of Ironton. The claim has a fifty-foot tunnel upon it, and the show for a large body of mineral is very good. This claim is one of the group known as the carbonate claims. The purchasers will develop the property as rapidly as possible.

NATIONAL BELLE.—It is currently reported that the National Belle lode has been sold to Eastern capitalists for $180,000 in cash. The National Belle is on Red Mountain, and is situated within a few hundred yards of the town of Red Mountain.

TOMICHI DISTRICT.

LEGAL TENDER.—A body of carbonates and galena carrying from $75 to $100 was struck recently.

DAKOTA.

FATHER DE SMET.—The superintendent reports, July 8th: Herewith express company's receipts for bar No. 162, containing 1012·6 ounces of gold, the result of run of mill for last half of June. We are now beginning to recover from the effects of the disastrous storms and floods which have prevailed during the past three months. At the mine, every thing is running well, and the work of developing and opening up new ground (which was stopped on account of scarcity of fuse) will go on again. The body of ore on the third level from which ore is mined did not equal our expectations as to size. I have just started a cross-cut from this level easterly, to cut the Golden Gate vein, which has never been touched on the third level. The superintendent's report for the week ended July 15th shows: Ore extracted from first level, 800 tons; second level, 700 tons; third level, 600 tons. Ore milled, 2100 tons. Golden Gate header in 137 feet and finished.

IDAHO

A copper mine on Lost River, owned by Mr. Williams and H. Stevenson, of Hailey, has been sold to Brown & Brother, of New York, for $40,000; $2000 were paid cash down yesterday, and a working bond given until November 1st on the balance. The intention of the purchasers is to work the property from the present time to November 1st, and if it proves up what it is believed to be, the company will erect a matting furnace after making the final payment.

MEXICO.

REAL DEL MONTE.—The *Financier* says: Mr. Landero, the director-general of the Real del Monte Company, has shown his sound good judgment in moving the large pumping-engine from the Acosta mine, in the Real del Monte District, to the San Pedro mine here, where he has struck a very wide and rich lode at a depth of 640 varas. This, I am told, will lead to the stockholders getting some fat dividends, as this company owns quite a number of good mines around the San Pedro, such as the following: San Juan, Jacal, Candado, Rosario, Guatemoczin, Milanesa, etc., which it has not been able to work fully, owing to the water coming so rapidly and in such large quantities. Not only will this do good to this company's properties, but also to all mines around belonging to other companies.

MICHIGAN.

COPPER.

COPPER FALLS.—The *Mining Gazette* says: The fiscal year of the corporation ended June 30th, during which time the mine afforded, from one head of stamps, 469 tons 255 pounds of mineral, 256 tons 130 pounds of which were taken out during the last six months of the year. The company is now increasing the size of its dressing-works by an addition of 44 by 48 feet to the wash-floors, which will be fitted up with twelve Collom's jiggers and four of Evans's slime-tables, to accommodate another head of stamps. A contract for a large boiler has been let, which will supply the necessary steam for the enlargements under way, which will be available before navigation closes. A large storage-shed for coal has been erected at the stamp-mill and a new coal dock has been built at Eagle Harbor.

HURON.—Last Saturday, the machinery in the new dressing-rooms on the mine

Digitized by Google

was put in motion for the first time, and worked well. A few minor details are perfecting, and it will not be many days now before the stamp-mill will be run regularly on rock for the mine.

IRON ORE.

The following table from the Marquette *Mining Journal* exhibits in gross tons the total lake shipments of iron ore from upper peninsula ports the present season, up to and including July 18th, together with the amount shipped from the same ports during the corresponding period of last year:

Name of port.	1882.	1883.
Escanaba	796,720	546,455
Marquette	442,978	210,449
L'Anse	21,962	20,998
St. Ignace	14,675	5,426
Total	1,276,335	783,327

Showing a decrease of 493,008 gross tons.

HEWITT.—At the mine, preparations are making to sink a working-shaft into the deposit recently discovered by the diamond drill, and where there are, making due allowance for the dip, at least 20 feet of ore. The management is under the impression that this newly-discovered deposit is merely a continuation of that in which the present workings are situated, and which swings off to the south and east, and on that reasoning predicate the belief that it is one of large extent.

MONTANA.

ALICE.—The winze from the 700-foot west drift at the Alice has reached the 800-foot level and exploration-work westward is prosecuted. Work has been resumed in the bottom of the main shaft of the Magna Charta, and the shaft will be sunk to the 600-foot level, which will be opened up at once. The Alice mills are making a remarkably steady run, and are crushing more quartz than ever before; 90 tons of ore are treated every twenty-four hours.

TIDAL WAVE.—Gideon & Root have sold the Tidal Wave mine, near Silver Star, to McCormick & Co., of Salt Lake, for $40,000. The ore on the dump was sold for an additional $2000.

NEVADA.

CHRISTIE.—The Eureka *Sentinel* reports that the owners of the mines at Mineral Hill, John Spencer, John McCabe, J. C. Crombie, Amos Plummer, and William Fleming, who had sold the property to the Christie Company, have begun suit in the District Court against that company and M. D. Munger, P. D. Barker, and H. G. Catlin, to foreclose mortgage, in default of payment of $80,000, in the form of two notes of $40,000 each, which fell due January 1st and July 1st, 1883, with interest on the same at six per cent per annum. Coupled with the suit, an injunction is prayed for to stop the taking out of ore from the mine until a settlement is reached. The $80,000 is a balance only, as a considerable sum has already been paid on the purchase.

MARTIN WHITE.—The mine is now furnishing about 10 tons per day, which is not enough to keep the twenty-stamp mill running. As the mill will crush 1200 tons per month, it will be some months before an amount sufficient to justify starting it has accumulated.

WALES CONSOLIDATED.—Henry Boyle has commenced proceedings in the Superior Court at San Francisco to restrain the Wales Consolidated Gold and Silver Mining Company, Eureka District, Nevada, from collecting by sale the stock assessment of 25 cents a share on the capital stock, alleging that the assessment is illegal.

RICHMOND CONSOLIDATED MINING COMPANY.—The report of the directors, prepared for presentation at the meeting, states that the mining profits for the year ended February 28th is £42,180 3s. 5d., and the net profit £30,258 7s. 10d. When it is remembered that during the whole of the year one furnace only has been running, that the ore has been of low grade, and that an exceptionally large amount of dead-work has been done, which has been charged to working expenses, this result is not unsatisfactory. Out of this £30,258 7s. 10d., with £26,352 18s. 4d.—the balance brought forward from last year's account—the directors have paid in dividends during the year £40,500, and £1632 19s. 5d. for extraordinary expenses in connection with the defense of the mine and the lawsuit with the Albion Company, leaving a balance on February 28th, 1883, to the credit of revenue of £14,478 6s. 9d., and the reserve of £75,000 intact. During the year, 17,088 tons of Richmond ore and 3451 tons of purchased ore have been smelted by the above furnace; and 8387 tons of low-grade Richmond and 108 tons of purchased ore have been smelted by the No. 4 furnace, working in connection with the refinery. The total production for the year from both furnaces is 14,940 ounces of gold, 508,362 ounces of silver, and 4027 tons of lead. The amount received during the year on the sales of the gold, silver, and lead is £396,669 12s. 6d., and the estimated net value of the bullion in transit and at the works, unrealized on February 28th, 1883 (after allowing for all unpaid refining and marketing expenses) is £116,172 19s. 9d.—together, £512,842 12s. 3d.—from which has to be deducted the value of the bullion in hand February 28th, 1882, then estimated at £206,080 2s. 8d., and £94,367 18s. 6d. paid for marketing expenses, refining, freights, commission, brokerage, etc., leaving £212,394 11s. 1d., as the net value of the bullion produced in the year. The cost of mining and hauling, dead-work, smelting, purchased ore, renewals and repairs, and all other working and general expenses at Eureka being £170,591 0s. 6d.; the profit for the year on mining, smelting, and refining is—with £367 12s. 10d. received for sundries—£42,180 3s. 5d. The decrease as compared with last year is caused, not only by the falling off of the reserves of ore, but also by the ore itself being of low grade—averaging only $49.93 per ton, as against $53.46 last year, and $66.11 the previous year. The yield per ton of ore (Richmond and purchased together) has been this year $44.19, as against $49.41 last year. One large furnace was at work until November 15th, when it was shut down, and a smaller one started in its stead. The No. 4 furnace, working for the refinery, was shut down on October 2d, the supply of ore being then insufficient to keep it in work; it was, however, restarted on January 15th, and has been at work continuously since that date. The bullion has realized 82½ per cent of the "Eureka standard assay value," as compared with 77 per cent last year.

The expenses of mining have increased from $10.48 to $13.01 per ton of ore extracted: but this is explainable by the fact that, while the number of tons of ore mined has been considerably less, the expenditure on dead-work, which has been heavier than usual, is included in the mining expenses. The cost of retimbering the main shaft and repairing the air-compressor has also been included in these expenses. The smelting expenses have been reduced from $13.51 to $11.66 per ton. The refinery has been working satisfactorily, and the expenses have decreased from $14.27 to $13.80 per ton of bullion treated. During the year, 10,540 tons of lead have been sold, the stock in hand being now reduced to about 8000 tons. The price is about 4·50 cents per pound at New York, or £18 per ton of 2000 pounds. The exploratory work done in the mine during the year is very large, and consists of 8642 feet of drifts, 322 feet of winzes, and 731 feet of rises, making a total of 9695 feet, as compared with 6907 feet last year. These works, as well as the smelting operations, have been carried on continuously throughout the year, notwithstanding that extensive repairs had to be made to the air-compressor and to the main shaft, and the machinery at the furnaces and refinery kept in efficient working order. The directors regret that up to the present time no large body of ore has been discovered; small pockets of good ore, have, however, been found on the 200, 700, 800, and 900 levels, and low-grade ore and ledge-matter in several other places. Connection has been traced in the ore from the 600 down to the 900 levels, thus establishing the fact that there is at this part of the mine an ore-channel making downward. The 1050 level is now pushed forward, and a fissure has been met with, which is followed. Some iron oxide, assaying $2 per ton, has been found, which is a promising indication. The limestone is favorable for ore, being similar to that in which the other ore-chambers were found in the higher levels. The exploratory work in this level is slow and expensive, on account of the imperfect ventilation; a rise is now going up from the 1050 to the 900 level, to avoid this. A new level has been started at 100 feet, to explore the large extent of ground above the 200 level. Explorations have also been carried on at the Hoosac mine, but no discoveries have been made as yet. An offer of purchasing the Williamsburg mine, situated about two miles from the Richmond, having been made, the company purchased it for £3000. Hoisting-works have been erected and explorations have been commenced; a mass of iron oxide, carrying some lead and silver, was soon met with, and in a recent letter Mr. Probert states that a good find of lead ore has just been made, containing as much as 60 per cent of lead and some silver. This is very satisfactory, as great difficulty has been experienced lately in preventing a heavy smelting loss, owing to the percentage of lead in the Richmond ore being as low as 12 per cent.

COMSTOCK LODE.

UNION CONSOLIDATED.—Mr. William Patton, superintendent, presented the following report at the annual meeting:

RECEIPTS.

Balance from last statement	$1 95
From other mines, for labor, etc.	61,596.25
From San Francisco office, drafts on the president	353,610.57
Total	$415,208.77

DISBURSEMENTS.

Salaries, exchange, etc	$5,388.94
Labor, supplies, etc	266,481.16
Union shaft, one third net expenses	102,790.81
Reduction of ore	30,210.57
Legal expenses	1,610.25
Taxes	5,709.27
Sutro tunnel, royalty on ore	2,968.86
Total	$415,159.86
Balance cash on hand	48.91
	$415,208.77
Gross expense	$415,159.86
Received for labor, etc	61,596.25
Net expenses	$353,563.61

On the 2900 level, the joint Sierra Nevada west cross-cut, which, at date of my last yearly report, had been advanced to a point 74 feet from the joint Sierra Nevada winze, has been extended 159 feet, making a total length of 233 feet from the winze. Water being encountered, the work was temporarily discontinued. The main south drift from the joint winze station, which was started in July, 1882, was connected with the main north drift of the Mexican Company in December last, completing a much needed air-way for this level. A joint Mexican east cross-cut was immediately started on our south line, and has been extended to a point 243 feet from the main north lateral drift. From this point, north drift No. 2 has been extended 82 feet. In January last, a joint Sierra Nevada east cross-cut was started from the joint Sierra Nevada winze and has been extended to a point 287 feet from that winze. When in a distance of 130 feet from the winze, the drift passed through a vein of ore 11 feet wide on the bottom of the drift and six feet wide on the top. The assays averaged $21 per ton. Work done on this ore-vein, since that time, has shown it to extend up 20 feet, and south 63 feet in our ground. In April last, a joint Sierra Nevada winze was started down from the joint east cross-cut, at a point 141 feet from the west side of the ore-vein. This winze reached the 3000 level on June 5th. In March last, an east cross-cut was started from the main south lateral drift, at a point 170 feet south of the joint Union-Sierra Nevada winze, down from the 2500 level, and extended to a point 93 feet from the south lateral drift. The 3000 level was reached from the joint Sierra Nevada winze down from the 2900 level, on June 5th. After cutting out a station, a joint Sierra Nevada west drift was started, which is now in 74 feet, passing through favorable looking vein-matter and quartz, giving low assays. This drift will be continued on a westerly course, to cut and explore the ore exposed on the 2900 level. While our explorations during the past year have as yet shown nothing of value, it is possible that the ore-vein passed through by the 2900 joint Sierra Nevada east drift will develop a valuable ore-body in our ground when the 3000 and 3100 levels are opened up. The drift west from the 3000 station of the joint Sierra Nevada winze (now cut 74 feet) has already passed through much more quartz than was shown east of the ore-vein on the 2900, which is no doubt a new formation coming in in depth. The ore-vein exposed on the 2900 level should be struck within the next 20 feet; and should it be found on this level, its value as a new development will be greatly enhanced.

NYE COUNTY.

TYBO CONSOLIDATED.—The twenty-stamp mill of this company is to be started up soon.

NEW JERSEY.

The diamond drill explorations at Port Oram by the New Jersey Iron Company have resulted in striking a vein, and the workmen have gone over on the hanging-wall and are boring another hole to prove the vein already found.

NEW MEXICO.

BILLING SMELTER.—From Socorro comes the news that the graders have completed their work on the Billing smelter, and the surveying corps is now twelve miles from Socorro, and expects to reach the Magdelenas in two weeks. The track-layers are within a mile of the smelter; but the greatest labor yet remains, a bridge 100 feet long to be built. The prospect is, that the contract for the main track between Socorro and Kelly will not be let before the 1st of September. Every thing will be completed by the 15th of August, and reduction commenced by the 1st of September. Ore from the Kelly mine is now arriving, and there will be three thousand tons of ore in the bins when the furnaces blow in. One hundred tons per day will be taken from the mine after that time. The contractors for freighting this ore from the mine are now hauling fifty tons per day, at five dollars per ton. By next summer, Mr. Billing will also erect refining-works at Socorro.

SIERRE GRANDE.—We have it from a good source that the mine is pretty thoroughly "cleaned" out. The manager, Mr. Robert Bunsen, will leave Lake Valley on the 15th ult.

PENNSYLVANIA.

The Susquehanna Mining and Smelting Company has put its smelting-works at Sunbury in operation, and on the 19th, at six P.M., made the first tapping of its reverberatory furnace. The furnace was charged at about one o'clock with thirty-two hundred-weight of ore. The company has opened three veins of ore, and has at least 5000 tons developed in sight in its drifts, averaging 60 per cent of lead. The lead produced will average from ten to fifteen ounces of silver to the ton. The company is erecting another furnace which will soon be in operation.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, July 27.

Business has been better and of a more widespread character than last week in the mining market, but prices have not materially changed. The fancy stocks dealt in have generally been strong, while the high-priced stocks, which have been but moderately dealt in, have been weak. Sierra Grande suffered a sharp decline in the early part of the week, but improved at the close. Horn-Silver has also declined. We give a summary of the market below. The total number of sales aggregates 235,354 shares, as against 115,559 last week.

The Comstock shares have shown more activity than usual this week, and prices have been steady. California was quiet and steady, selling from 28@32@30c., assessment paid. Consolidated Virginia had a very active business at irregular prices; it sold from 37@31@33c. Sierra Nevada was moderately dealt in and was strong, selling from $3.90@$4.15@$4.10. Union Consolidated records moderate transactions at steady prices, selling from $4.75@$5@$4 90. Mexican was quiet and steady at $2.85. Yellow Jacket sold at $3.25, and Best & Belcher at $4.15. Sutro Tunnel was actively dealt in, and was steady, selling from 20@19c.

The Leadville stocks were very quiet, and were steady. Amie was a trifle strong, under a small business, and sold from 11@15@14c. Chrysolite records a small business at steady prices, selling from $1.10@$1.15 Dunkin sold at 20c. Hibernia was very quiet at 4c. Iron Silver, with a business of 800 shares, sold at $3. Little Chief was weak, under small transactions, selling from 50@40c. Little Pittsburg records a small business at steady prices, selling at 66@65c. Climax sold from 7@8c.

The Bodie stocks were almost neglected, and were steady. Bodie sold at 80c. Standard was moderately dealt in at steady prices, selling from $6.75@$6.50. North Standard sold from 7@10c., with a small business.

The Tuscarora stocks were quiet and steady. Grand Prize sold at 32c. Belle Isle was quiet and a little weak, selling from 44@38c. Navajo was quite strong, under moderate transactions, selling from $2.90@$3.35@$3.15. North Belle Isle sold at 40c. Independence had a fair business at strong prices, selling from 50@55c. Elko Consolidated was quiet and steady at 18@20c.

In the miscellaneous list, Alice was quiet and steady selling from $2.50@$2.75. Caribou sold from 13@14c., with a moderate business. Eureka Consolidated has been quite weak, owing to an assessment of one dollar per share having been levied by the company, and has sold from $5.50 $4.15. Green Mountain had a fair business at steady prices, selling from 72@80c. Horn-Silver was quiet and weak, selling from $7.63@$7.25. Northern Belle displayed some strength under a moderate business, selling from $6.38 $7. Robinson Consolidated has had a fair business at stronger prices, selling fro m 60@70c. Sierra Grande was quite weak at one time, but rallied a little toward the close; it sold from $1@86@97c. Silver King was quiet at $6.88. Our correspondent in San Francisco gives, elsewhere, some points regarding this property. Stormont has been actively dealt in at steady prices; it sold from 35@37c.

Alta-Montana has been very active at prices a little stronger than of late; it sold from 3@5c. Decatur was quiet and irregular, selling from 3@5@4c. Eastern Oregon continues to gain strength, and has been very active; it sold from 76@81c. Harlem was quiet and steady, selling from $1.30@$1.35. Oriental & Miller has been quiet and steady at 13@14c. Sonora Consolidated has had an active business at strong prices; it sold from 24@28c. South Hite at one time was quite strong but became very weak at the close; it sold from 10@27@3c.

The officers of the Iron Silver Mining Company have issued a statement to their stockholders, showing that, after paying the June dividend of $100,000, the company had a cash balance on hand equal to $172,906.

New Mexico copper properties have attracted a considerable share of interest among English capitalists. We understand that the Valverde has been sold, after negotiations which have been pending for nearly a year, and that the Santa Rita will also soon pass into the hands of Englishmen.

The Mackay & Revolution Silver Mining Company is a Utah mine which is now placing in the English market, with a capital of £150,000 in £1 shares.

MEETINGS.

Champion Mining Company, of Bodie, Cal., Room 2, Nevada Block, San Francisco, Cal. Annual meeting of stockholders and election of trustees, July 30th.

Consolidated Excursion Mining Company, Room 12, No. 80 Wall street, New York City. Annual meeting of stockholders and election of trustees, August 7th, at twelve o'clock noon.

Santa Eulalia Silver Mining Company, No. 82 Broadway, New York City. Annual meeting of stockholders and election of trustees, August 13th, at twelve o'clock noon.

Spring Valley Hydraulic Gold Company, No. 61 Broadway, New York City. Meeting of stockholders for the purpose of increasing the capital stock to $300,000, August 2d, at twelve o'clock noon.

DIVIDENDS.

The Boreel Mining Company has declared a dividend of fifteen cents per share, payable July 25th.

The Calumet & Hecla Mining Company, of Michigan, has declared a dividend of five dollars per share, payable August 15th.

The Consolidated Gold Mining Company of Georgia has declared its usual monthly dividend (the twenty-sixth) of four cents per share, payable on and after July 23d.

The Plymouth Consolidated Gold Mining Company has declared a dividend of fifty cents per share, payable immediately.

The Thomas Iron Company has declared a semi-annual dividend of five per cent.

PIPE LINE CERTIFICATES.

The petroleum market has gradually and steadily advanced, until to-day shows the strongest price for oil this week. A very active business has been done and considerable excitement has prevailed at the Exchanges. The only news from the oil-fields was the report of the production of the new districts. For the Cooper tract, the production is 3401 barrels from 97 wells, an increase of but 86 barrels from a week ago, and the increase is explained by the fact that six oil-wells were torpedoed. The Balltown District showed a production of 2223 barrels from 25 wells, an increase of only 23 barrels. There has been no further news from the oil regions, but a strong monthly report is expected of the development-work done.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.

BULLION MARKET.

NEW YORK, Friday Evening, July 27.

There has been a slight improvement in silver in London the past week, which has been reflected in our market; but this change does not promise much steadiness.

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.
July 21	50 5-16	109⅞	July 25	50 7-16	110⅛
23	50⅜	110	26	50 7-16@½	110⅛
24	50⅜	110	27	50 7-16	110⅛

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29-29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14⅛ per cent, to arrive at actual value.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended July 27th, as compiled from various sources, amounted to $228,500, as against $131,262 reported for the previous week. The receipts from January 1st, 1883, to date are $6,523,974.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended July 21st	$321,424
Corresponding week last year	2,469,426
Since January 1st, 1883	7,395,359
Corresponding period last year	38,841,760

Imports.

Week ended July 21st	$193,688
Corresponding week last year	60,695
Since January 1st, 1883	7,380,290
Corresponding period last year	2,082,684

Foreign Bank Statements.—The governors of the Bank of England, at their weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 4 per cent. During the week, the bank gained £417,000 bullion, and the proportion of its reserve to its liabilities was raised from 41 7-16 to 44¼ per cent, against 39 5-16 per cent at this date a year ago. June 26th, the bank gained £60,000 bullion on balance. The weekly statement of the Bank of France shows losses of 300,000 francs gold, and 1,100,000 francs silver. The statement of the Imperial Bank of Germany shows an increase in specie of 6,720,000 marks.

METALS.

NEW YORK, Friday Evening, July 27.

Copper.—The market is dull and lifeless. Manufacturers are well supplied, and there is no outside interest in the metal. It would be difficult to realize more than 15c. for Lake copper, if a holder were forced to sell, while those buyers coming into the market must pay 15⅛c. For other brands, of which there is no abundance, the figures range between 14@14⅛c. The latest cables place Chili Bars at £63 12s. 6d.@£64, and Best Selected, £69@£70.

The following are the Board of Trade returns:

	Jan. 1 to June 30.		
	1883.	1882.	1881.
Imports:	Tons.	Tons.	Tons.
Pure in pyrites	8,658	8,499	6,941
" precipitate	10,616	8,876	10,271
" ore	6,742	5,835	6,508
" regulus	5,260	3,691	2,447
Bars, cakes, etc	17,297	15,977	14,014
	48,573	42,878	40,154
Exports:

Brass at 70 per cent	1,694	1,541	1,524
	23,849	20,331	21,736
Foreign	5,739	5,808	5,673
	29,588	26,139	27,409

Tin.—There has been considerable excitement during the week, the market advancing to as high as 22c. for spot Straits, while a large business, also, was done in futures. At the close, the market was weaker, 350 tons having arrived at the dock. The metal is strongly held, and as there is no more tin due until late in August, it is probable that it will again rally. We quote now 21⅝@21¾ for round lots Straits, spot. England cables £94 5s.@£94 10s.

Lead.—Beyond jobbing lots, aggregating probably from 300 to 400 tons, at 4·30c., there is nothing to report. Holders here of the 2000 tons of Richmond lead, 1500 tons of Pueblo, and 600 tons of Germania are firm, and thus little spot stock is available at current figures. There is no trouble, however, in supplying current wants from the West. We understand that Common lead has been offered here at 4·25c. without finding buyers, and that Corroding has sold in Philadelphia at less than 4·35c. The metal is not in a very strong position, and there are many who look for lower values at an early date. London cables £12 10s. for soft Spanish.

Messrs. Everett & Post, of Chicago, wire us as follows to-day:

As there are no buyers in the market, it is difficult to give figures. Prices are nominally 4·10c. for Common and Refined. Sales aggregate 200 tons. Offerings, however, are moderate.

Spelter.—There have been some sales at private terms, and we learn that new ordinary Domestic has been offered at 4·30c., a figure which, with high prices of ore, a number of Western producers can certainly not meet. London cables £15 5s. for Silesian.

Antimony.—The tone is somewhat firmer, owing chiefly to the fact that spot stocks are light. We quote 9¼@9⅝c. for Hallett's and 10¼@10⅝c. for Cookson's.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, July 27.

According to the Board of Trade returns, the exports from Great Britain to this country during the first six months of the year were as follows:

	1881.	1882.	1883.
Pig-iron	177,294	237,814	133,773
Old iron for re-manufacture	44,643	53,559	33,963
Steel unwrought	49,345	92,990	22,510
Tin plates	80,253	104,021	100,462
Hoops and sheets	11,940	13,185	14,6.2
Bar, angle, bolt, and rod	6,271	12,383	6,084
Railroad iron, all kinds	159,309	123,442	34,425

This shows a gratifying decrease all round.

American Pig.—We discuss editorially the valuable statistics compiled by the American Iron and Steel Association, which throw a flood of light upon the situation. The market has not materially changed since our last. No. 1 Foundry is scarce, and commands higher prices readily, while No. 2 is in ample supply and is rather dull. Gray Forge is fairly steady. We quote $22@$23.50 for No. 1 Standard to Choice; $21@$21.50 for Ordinary No. 1; $19@$20.50 for Ordinary to Choice No. 2; $18@$20 for Inferior to Choice Gray Forge. Bessemer pig is dull at $20.50 bid, $21 asked, London cabling 50@51s. Spiegeleisen is quiet at $30@$31.

At the Metal Exchange, efforts are making to depress the market. During the week, the following transactions have been recorded: Monday, 100 tons No 1, October delivery, at $22; Tuesday, 200 tons No. 1, October delivery, $21.87½, and 200 tons, November, $22.25; Wednesday, 200 tons, October, $21.87½; Thursday, 100 tons, October, $21 87½, and 200 tons, November, $22.12½; and to-day, 100 tons, September, $21.62½, 100 tons, October, $21.75, and 400 tons, November, $22.

Scotch Pig.—There has been an advance in freights, which are now quoted by cable 9@10s. from Glasgow to this city, which induces importers to assume a firmer attitude, though business is not large and arrivals continue light. We quote ex ship: Coltness, $23.75@$24; Langloan, $23.75@$24; Summerlee, $23@$23.50; Dalmellington, $21@21.50; and Eglinton, $21.

At the Exchange, the following cable quotations were received: Coltness, 61s.; Langloan, 60s. 6d.; Summerlee, 57s. 6d.; Gartsherrie, 57s. 6d.; Glengarnock, at Ardrossan, 55s.; and Eglinton, at Ardrossan, 49s. 6d. Warrants to-day were 47s. 3d.

Rails.—We hear of transactions aggregating 10,000 tons, in small lots, for delivery till the close of the year at $38 at mill for larger lots, and $38.25 and $38.50 for small parcels. The struggle of the Bethlehem Company with the Amalgamated Association is watched with much interest. It does not now seem likely to extend to the other mills, especially since the company has been gaining ground of late.

Old Rails.—Beyond a few unimportant sales, there is very little going on. We quote Ts $21.50@$22.

Scrap is dull at $22@22.50 except for No. 1.

Philadelphia. July 27.

Pig-Iron.—The strong companies are refusing to sell Foundry Iron at less than their own figures, which range from $22@$23.50 for No. 1 iron, and $19.50@$20 50 for No. 2. The special brands command $23.50 without difficulty, and standards average $22.50. These high prices prevent the closing of large contracts at present. Buyers are anxious to cover their summer and fall requirements, and have made numerous offers, which have not been accepted. The opinions on the future probabilities of the market are not uniform. Some believe that a break must come, and that fall supplies can be had on some reasonable terms; but the producers have canvassed the situation pretty thoroughly, and refuse to yield. The aggregate of business is large; perhaps as large as though individual transactions were for much larger amounts. Forge iron of nearly every kind is in abundant supply. The exception is in special brands of Forge, some few of which are pretty well sold up, and could be sold up for ninety days if buyers' offers were accepted. The stocks of all kinds are large, but not troublesome. They will soon disappear when the rolling-mill men begin to purchase. Most of the business transactions are in small lots. There are inquiries for 1000-ton lots, but makers are not disposed to extend concessions asked for. Average selling prices are $17.50@$18, with some at $18.50, and a little at $19, furnace delivery.

Considerable activity has prevailed in Muck Bars, and prices have taken a little wider range, running from $33.50@$35.

Blooms.—Charcoal Blooms run from $57@$60 for average makes, with some inferior stuff a little below. The demand is fair. Anthracite blooms run from $48@$50. Some sales of Northern ore blooms have taken place.

Merchant Iron.—Nothing has taken place to induce change from the retail policy of the past month or two. Consumers are willing to pay higher prices for small lots to carry them over the dull season, hoping that the opening of the fall trade will bring more abundant supplies and lower prices. The rates usually quoted are 2·20@2·25c., but the larger consumers prefer to wait until they can secure stocks at 2·10c. or 2·15c., which they believe they can do. At present prices of gray forge iron, mill-owners do not think that there is room for such rates. The mills in the interior are taking a large share of the trade going, and prices are firm all around. Next month, large lots will be wanted, but orders will not be placed unless 2·15c. rates are satisfactory to manufacturers. A good many mills are working short-handed, and, when they make their full output, there will be an opportunity for lower prices. Some few sales of skelp iron have been made.

Nails.—For a few weeks past, shipments of nails have fallen off, though production has been kept up to the full capacity, and hence stocks are in better shape. Some contractors have placed sixty-day orders, and prices are firm at $3 in large lots, to $3.25 in small lots from mill or store.

Structural Iron.—The inquiries this week are far larger than usual supplies, and in one or two cases, terms have been agreed upon for large deliveries. Mills are well supplied by the steady retail demand. Quotations are steady at 2·40c. for Angle Iron, and a shading from 3·50c. on Beams and Channels, for large orders. The outlook is satisfactory to the manufacturers, and they will wait until larger buyers decide to buy, without yielding much from present figures.

Plate and Tank Iron.—Considerable business has been done in a quiet way, some of it at concessions of one tenth.

Steel rails range from $38@$40. More business is offered than taken. Old material is not selling at any price.

Pittsburg. July 26.

Several of the mills that have been idle for a week or two, making repairs, will resume in a short time. While an active fall trade is anticipated, it must be said that very little activity prevails at the present time, and that the disposition of the iron trade is to purchase as little as possible, and to wait as long as possible, in the hope of lower prices. There is a lack of that confidence which leads to activity. The large available supply of forge iron will continue to check any very active demand until it is actually disposed of. It is a constant threat to production and to steady prices. Quotations have not changed. Some kinds of iron have shown little improvement; but as long as buyers purchase only for temporary wants, the improvement will be trifling. A few consumers of forge iron have been endeavoring to negotiate for large requirements, but at prices below makers' views. Inferior Gray Forge is quoted at $17.50@$18. Offers have been made at $17 and under. No. 1 Foundry is $20@$21; Cold-Blast Charcoal, $28@$30; Bessemer iron sells at $21@$21.50. Sales of Muck Bar have been made at $34.

A good deal of Merchant iron is moving at 1·90c. and for cash at a little less. No very marked improvement is looked for until August.

Digitized by Google

A fair demand is maintained for nails, and the thirty days' suspension is working out good results. Gas and steam pipes have been sold in fair lots at 75 per cent off; Boiler tubes, 60 per cent off. Steel of low grade is cut by competitors, and there is nothing encouraging in the outlook.

Steel rails are in active demand at $38@$39, and heavy orders have been received for winter delivery. Large orders for cars and locomotives have been given out in this State, and the requirements in this direction and for all kinds of construction iron will be heavy, and will help to give strength to an already improving market.

Cleveland. July 24.

The market for the past two weeks has shown some slight improvement, consumers buying with more confidence and slightly better feeling on part of holders. There has been no pronounced advance in values, but it looks healthier. Best grades Foundry iron are not too plentiful and good softeners are in demand. We quote the same.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, July 27.

Anthracite.

Business is very dull, and we hear of numerous instances of concessions below the nominal circular rates, ranging from 25 to 40 cents, steam sizes being apparently most heavily affected. The question of increasing circular prices for August has been discussed, and the decision has been wisely reached that it will be best to let them alone, and it is urged by the best element in the trade that, unless matters take an exceptionally favorable turn, it will be most judicious not to meddle with them even in September and October. As it is, June prices fairly represent the market. Middlemen in many instances are backward in taking the coal they ordered in June, a proof that buyers have not been as numerous as they expected.

It is believed generally that there will be no interruption of full-time for the remainder of the year.

As yet, no news has come to hand concerning the doings at the meeting of the Western Association at Saratoga this week.

On the Western trade, the Buffalo correspondent of *Coal* says:

Stocks here are very low, but at Western points large. At some Western depots, the docks and yards are so loaded with coal in first hands that no more can be received; but as the places are feeders for still farther points which are bare of fuel, as soon as the army of small dealers in all sections realizes that the supply is under control, and will be furnished only just as it is wanted and no faster, perhaps it will purchase now instead of waiting until later in the season. There is evidently a determination to maintain, and if possible to advance, quotations by the committee, notwithstanding the dissatisfaction existing among the said army.

Bituminous.

There is absolutely nothing to report in the bituminous market, which remains stagnant, with low prices induced by the sharp competition among producers, the rivalry of the two leading regions, and the efforts of new classes of coal to gain a foothold in the market. Quotations remain nominally unchanged.

STATISTICS OF COAL PRODUCTION.

The Production of Bituminous Coal for the week ended July 14th was as follows:

Tons of 2000 lbs., unless otherwise designated.

	Week. Tons.	Year. Tons.
Cumberland Region, Md.		
Tons of 2240 lbs.	59,808	1,410,353
Barclay Region, Pa.		
Barclay RR., tons of 2240 lbs.	4,723	168,209
Broad Top Region, Pa.		
Huntingdon & Broad Top RR	3,563	103,339

BALTIMORE, July 23, 1883. GEORGE W. JONES & Co.

Something About Bread-Making.

By the process of bread-making it is intended to convert the flour of certain grains into a cellular structure, in which it is most easily chewed, saturated with the fluids of the mouth, and digested. In order to arrive at this end, alcoholic fermentation is resorted to from olden times, by introducing the same in the dough by means of brewers' yeast. Thus a small part of the flour is converted into glucose, which again is transformed into alcohol and carbonic acid. The former is recognized by its peculiar vinous odor, exhaled by the loaves, when sufficiently raised. Both gases produce the raising of the dough—that is, the porous and spongy appearance.

By this fermentation, the flour not only loses weight,

Digitized by Google

but the bread also attains qualities which may injure the process of digestion.

In order to evade these inconveniences, chemists have long ago searched, to impart the spongy structure of the dough by other means than yeast, respectively by substances evolving gaseous bodies, or which, in the oven, are transformed into gases themselves. To the best known belong the bicarbonate of soda and cream of tartar, certainly well known to all housewives. And with regard to most of the baking powders of the trade, they are mainly preparations containing these substances. However, it can not be said of any of them that they exert a beneficial influence on the system, not to speak of the adulterations to which most of them have lately been subjected.

We are glad to learn that *Prof. E. N. Horsford*, of Cambridge, Mass., who held the chair of chemistry in Harvard University, invented, some time since, a baking preparation forming an exception to those spoken of, which has already attained universal reputation.

The idea by which Prof. Horsford was guided, was not only to furnish a substitute for brewers' yeast, but also to provide those nutritious constituents of the flour lost in the bran in the process of bolting. These are the so-called phosphates, which are also the nutritive salts of meat, and of the utmost importance for the building up of the organism. If we take into consideration that the nutritive value of wheaten flour is from twelve to fifteen per cent less than of the wheat grain, and that this loss is now restored by Prof. Horsford's invention, then we must look upon it as of the greatest national economic importance. As Justus von Liebig, said: "The result is the same as if the fertility of our wheat fields had been increased by one seventh or one eighth."

Horsford's Acid Phosphate.

Tonic for Overworked Men.

Dr. J. C. WILSON, Philadelphia, Pa., says: "I have used it as a general tonic, and in particular in the debility and dyspepsia of overworked men, with satisfactory results."

MAPS.

IDAHO.—The Wood River Region of Central Idaho, giving the first correct Geography of that recently explored and remarkable Belt of Discoveries of Gold and Silver Mines on the tributary streams of the WOOD and LITTLE WOOD Rivers, on the Upper Waters of the SALMON RIVER, among the SAWTOOTH MOUNTAINS, and on the Forks of the BOISE RIVER; embracing the Mount Estes and Custer Mines on the north and the Oregon Short Line Railroad on the south. Prepared by Frank J. Scott. Scale, 5 miles to the inch. Size, 15 x 26 inches. In paper pocket Price, $1.

MEXICO.—Map of Mexico. Showing Railroads, Broad Gauge and Narrow-Gauge, Constructed; and Railroads Broad-Gauge and Narrow-Gauge, Proposed. This very large and finely-engraved Map, constructed originally by the government for official purposes, contains all the information obtainable by it, and shows minutely the towns and villages of the entire country. Scale: 26·6 Mexican Leagues to the degree, and 69·16 English Miles to the degree; also, Kilometrical Scale. 1881. Size, 53×41 inches. Printed in colors. Pocket form, $5.

MAP OF MINING CLAIMS ADJOINING LEADVILLE, California Mining District, Lake County, Colo. By Edward Rollandet. 1879. Mounted on muslin, $2.50. In cloth-bound covers, $2.

MINING MAP OF UTAH.—Showing the location of the Mining Districts, over an extent of territory 150 miles from North to South. Compiled from U. S. Government Surveys and other authentic sources. Scale, one inch to four miles. Colored. 1879. Pocket form. $1.50.

NEW SECTIONAL AND MINERAL MAP OF UTAH.—Pocket form. Compiled from the latest U. S. Government Surveys and other authentic sources, exhibiting the Sections, Fractional Sections, Counties, Cities, Towns, Settlements, MINING DISTRICTS, Railroads, and other internal improvements. Scale, one inch to eight miles. Colored, 1878. $3.50.

POCKET MINING ATLAS OF THE MINES OF THE UNITED STATES.—Showing the Mines of NEVADA: the Comstock Lode, the Eureka, Treasure Hill, and Tuscarora Districts; CALIFORNIA, including Map of the Bodie District; COLORADO, including the Leadville, Silver Cliff, San Juan, Caribou, and Central City Districts; DAKOTA, including Map of Deadwood; MONTANA, IDAHO, UTAH, ARIZONA, NEW MEXICO, LAKE SUPERIOR REGION, the SOUTHERN STATES. 1880. Printed in colors, and bound in flexible leather covers. Price, $1.

GREAT MAP OF THE WYOMING VALLEY.

This, the most elaborate and accurate topographical map ever made in this country, outside of the Coast Survey, covers an area of TWO HUNDRED SQUARE MILES, and the work upon it cost over $12,000. It represents a coal-field which produced in 1874 over 10,000,000 tons of Anthracite. The Map was constructed altogether from original surveys. Every Road, Colliery, Building, or land or property line existing at the time is accurately located. The surface configuration is shown by CONTOUR LINES TEN FEET APART, VERTICALLY; and the elevation of every point above sea-level is given.

But a small edition of this Map was printed, and the plates were then destroyed.

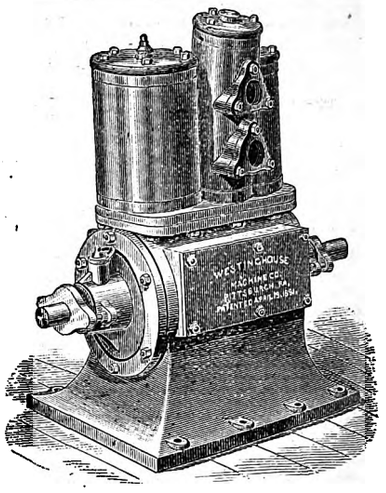
A few copies are for sale.

Price: On thick, heavy paper..... $25
On bond paper, for mounting..... 25

The six sheets can be mounted separately, or in a single roll 15 feet long by 42 inches wide.

Address,
THE SCIENTIFIC PUBLISHING CO.,
27 Park Place, P.O. Box 1833,
New York City.

SUPERINTENDENTS of Mines, Smelting-Works, Furnaces, etc., ENGINEERS, CONTRACTORS, and CONSUMERS of Mining and Engineering Supplies generally, will consult their best interests by frequent reference to the Advertising Columns of the ENGINEERING AND MINING JOURNAL. Its pages contain THE LARGEST LIST OF RELIABLE MANUFACTURERS AND DEALERS in these supplies, to be found in any paper published on this continent.



THE SMELTING OF COPPER

SWANSEA DISTRICT OF SOUTH WALES.

From the Time of Elizabeth to the Present Day.

By COLONEL GRANT-FRANCIS, F.S.A., author of "Swansea Charters," etc. Second Edition. Beautifully illustrated. London, 1881. Demy 8vo, 193 pages. Half bronze roan, with malachite insides and gilt top. Price $4. Quarto, large paper, half bronze roan, etc., $6. Among the illustration are a number of reproductions of scarce engravings.

DR. THOMAS M. DROWN, Secretary of the American Institute of Mining Engineers, announces that the fall meeting will be held in Troy during the second week in October. As the meeting will be devoted mainly to the reading and discussion of papers, the Secretary is making arrangements to print and circulate in advance any papers which the writers desire fully discussed, provided they are sent to him early in September.

THE closing down of the Harrison Reduction-Works, in Leadville, on account of scarcity of ore, is a significant fact, which the knowledge of the ability of the management to work as closely as local circumstances will permit makes all the more worthy of attention. The outside smelters, the Grant, Hill, Pueblo, Eilers, and Royal Gorge, are taking many of the large contracts, aggregating probably closely upon one half the output, while the six Leadville works are nearly capable of treating the entire product by themselves. Some of the heaviest producers, the Evening and Morning Star, the Iron Silver, and Silver Cord are shipping one half or one third of their output out of the camp, because the outside smelters are able to offer better terms than the local works. Utah works, too, have recently appeared as competitors.

VERY satisfactory progress has been made in our rolling-mills, steel-works, and blast-furnaces in the introduction of the best types of modern steam-engines, and we have had occasion repeatedly to note that in some of our latest silver and gold mills a spirit of true economy has prompted managers to call for similarly good work. As our mines grow deeper, and fuel in many instances becomes more expensive, it will be well for mining engineers, too, to look further than the average hoist. In many instances, the use of cut-off engines will prove economical. Automatic cut-off engines will save but little when the mines are not deep and when the hoisting is done rapidly, because the variations in the load between the full weight at the beginning and complete throttling at the end of the lift are so great in so short a space of time. Nor is it advisable to use an automatic cut-off when hoisting slowly from shallow depths; but when the weight of the hoisting-rope is not well balanced, it is best to arrange the automatic cut-off by means of a governor, because the handling of a cut-off lever is not desirable.

FOR many months, the market reports of both crude and manufactured articles have had but one story to tell: that of a constant decline in values under the pressure of a heavy production and the influence of an unparalleled timidity of buyers. In a number of trades, leading firms have succumbed, and in many others there is a feeling of doubt and uncertainty as to the future, which has led to a conservative dealing so general that business has fallen off very much, while ready money has been accumulating at such a rate at financial centers that it does not bring more than two per cent, and often less. This universal desire to retrench and to hold surplus funds in reserve for any possible emergencies has affected not only the stock exchanges, whose dealings with the outside public have dwindled away completely, in spite of many efforts to engineer a return of the old interest, but legitimate trade in all branches has also suffered. That this should be so in spite of promising crops and a fair degree of activity on the part of our railroads, is a subject over which many people are anxiously pondering, and while there is little disagreement as to the existence and extent of the evil, we have yet to hear of any plausible explanation of the causes.

THE German iron-masters have been indulging in a somewhat rambling discussion as to what measures should be taken to get their ship-builders to stop buying their iron ship plates and shapes in England and to take them from home mills. The occasion was furnished by the reading of a paper by Herr JACOBI, of Sterkrade, before the Society of German Iron-Masters, who gave the following reasons for the inability of the German works to compete with their foreign rivals. A ship-builder applying to an English firm for prices for raw material, for a ship of given tonnage and value, gets an offer to furnish it for a lump sum. A German works calls for a specification, picks out what part of the work it can do, estimates on it, and passes the rest of the work over to some other mill, so that the builder has to deal with a number of establishments instead of with one, and must go through a long process of figuring to get at the cost. Moreover, the English iron is much cheaper. This, the Germans assert, is because they do not currently make in large quantities material as poor as the plates produced in Middlesborough. They assert that if they could get Lloyd's to make special reductions for proved increase in the mechanical qualities of the raw material, and if the German railroads would put down their rates to compensate the mills for the fact that raw material for ship-building is on the free list, they could compete for the orders of the German yards. There is undoubtedly much truth in the assertion that English plates and shapes are very often of such very poor quality that many of the mysterious disappearances of vessels must be attributed to this fact; but it will take a long time before German mills can as promptly and as satisfactorily fill orders as their English rivals for the German merchant marine. The German navy is now almost exclusively supplied by the works of the country.

IN a quiet way, copper is the subject of considerable discussion in the trade, and there are many who are inclined to take a hopeful view of its future. It is argued by many that prices can not go any lower, while the likelihood is, that they will move upward. The situation is tolerably clear on this side of the Atlantic. We have shipped abroad, and are still shipping, large quantities of refined and crude copper and furnace material and ores, and have latterly begun to export largely also manufactured goods. At present prices here and abroad, this movement will continue unabated, and it may increase in volume should prices abroad harden. They are now under an artificial influence; a business firm which is well known as having been formerly an extensive speculator in tin having been holding the market for a long time. Should its movement prove successful, we may look forward to a hardening of prices here. But the trade must also face the possibility

Digitized by Google

of a failure of the speculation alluded to; and in that case, the future of our market would not be so bright. It might check our shipments, and turn into home channels considerable quantities of metal, under which the market would find it hard to rally. So far as our production goes, it is undoubtedly heavier in almost every quarter than it has been. The lake mines are in the aggregate increasing their output, and, taken all in all, the Southwest, including Arizona and New Mexico, will be ahead of last year. The Northwest, Montana principally, is developing wonderfully, but the great bulk of the material produced there goes abroad. The weakest spot in our markets, the outside brands, are now showing comparatively more strength than lake, a proof that for the present the supplies available to our refiners are not by far as heavy as they used to be. Altogether, the situation here is good; but it is imperiled by whatever may happen in England, and there the future is not so well defined as it is here.

EVIDENCE is accumulating that the Connellsville coke interests are to be consolidated in the hands of a few. The famous region has been the scene of an unparalleled development during the past few years, and its expansion of business has been the cause of a lively struggle by a number of great railroads. The Baltimore & Ohio has just appeared as a formidable rival of the Pennsylvania Railroad, and now the Vanderbilt-Gowen interest appears upon the scene, in a characteristic manner. Mr. VANDERBILT has taken the first step by building the Pittsburg, McKeesport & Youghiogheny Railroad from Pittsburg, with a branch into the coke regions, and is now at work preparing for the second one, that of securing a goodly share of the business of the region. It is stated, with much show of authority, that a syndicate has been formed embracing such men as H. C. FRICK, A. A. HUTCHINSON, with their thousands of coke-ovens, THOMAS CARNEGIE, DAVID HOSTETTER, D. A. STEWART, THOMAS MELON, and others, who, with the VANDERBILT interest, have been securing the co-operation of some coke-producers and have acquired control of the make of others. Possibly, the depression which has made so many of those interested uneasy during the past months may have obtained a share of its intensely acute character artificially, the object being to make the weak-kneed feel the blessings of submission. It is not likely that rival railroad interests will stand idly by and see their business thus pass to the control of a new-comer, and the producers of the region may have the pleasure of seeing three rich corporations bidding for their patronage. Ultimately, however, we presume the majority of the ovens might as well be branded "P.," "B. & O.," or "V."

Blast-furnace men will look upon this movement with alarm. With the Lake Superior iron ore miners holding the candle as high as the price of foreign iron, *plus* the duty and freights, will allow, and the coke-railroad alliance keeping the fuel at the highest notch which the "business will bear," their prospects of making large profits in times of prosperity, or any at all in periods of depression, are meager indeed. They should sell out to a "syndicate," and shift the burden on the rolling-mills and foundries.

ON THE SUPPOSED HUMAN FOOT-PRINTS RECENTLY FOUND IN NEVADA.

During the past summer, various accounts have been published of the discovery of human foot-prints in sandstone near Carson, Nevada, which Prof. O. C. Marsh has recently written on in the *American Journal of Science*. The locality is in the yard of the State's prison, and the tracks were uncovered in quarrying stone for building purposes. Many different kinds of tracks were found, some of which were made by an animal allied to the elephant; some resembled those of the horse and the deer; others were apparently made by a wolf. There were also tracks made by large birds.

The foot-prints occur in series, and are all nearly in the same horizon. Some of the smaller tracks are sharp and distinct, but most of the impressions are indefinite in outline, owing apparently to the fact that the exact surface on which they were made is not usually exposed.

The supposed human foot-prints are in six series, each with alternate right and left tracks. The stride is from two and a half to over three feet in extent. The individual foot-prints are from eighteen to twenty inches in length, and about eight inches wide. The distance between the line of right-hand and left-hand tracks, or the straddle, is from eighteen to nineteen inches. The size of these foot-prints, and especially the width between the right and left series, are strong evidence that they were not made by men, as has been so generally supposed. A more probable explanation is, that the impressions are the tracks of a large sloth, either *Mylodon* or *Morotherium*, remains of which have been found in essentially the same horizon. In support of this view, it may be said that the foot-prints are almost exactly what these animals would make, if the hind feet covered the impressions of those in front. In size, in stride, and in width between the right and left series of impressions, the foot-prints agree closely with what we should expect *Mylodon* or *Morotherium* to make. The geological horizon of these interesting foot-prints is near the junction of the Pliocene and Quaternary. The evidence, at present, appears to point to the Equus beds of the Upper Pliocene as the nearest equivalent. Since the above communication was read, Professor Marsh has had an opportunity of examining photographs and casts of the Carson foot-prints, and is confirmed in his opinion that the supposed human tracks were made by large Edentates. The important fact has recently been determined that some of these tracks show impressions of the fore feet. The latter are somewhat outside of the large foot-prints, as would naturally be the case, if the animal changed its course.

MINERAL PRODUCTS OF THE UNITED STATES.

A report, entitled *The Mineral Resources of the United States*, is now in press, and will shortly be published by Mr. Albert Williams, Jr., Chief of the Division of Mining Statistics and Technology, United States Geological Survey, Hon. J. W. Powell, Director. This report is for the calendar year 1882 and the first six months of 1883. It contains detailed statistics for these periods and also for preceding years, together with much technical and descriptive matter. The compilation of special statistics has been placed by Mr. Williams in the charge of leading authorities in the several branches, and the results will therefore be accepted with confidence. The following totals of the production of the more important mineral substances are from advanced proofs:

Coal.—The only statistics in which the trade is interested are those relating to the amount of coal which is mined for and reaches the market. There is, besides, a local and colliery consumption which is usually disregarded in statistics, and which ranges from 5 to 6¼ per cent on the total shipments. Of what may be called the commercial product, the quantities in 1882 were: Pennsylvania anthracite, 29,120,096 gross tons; bituminous, brown coal, lignite, and small lots of anthracite mined outside of Pennsylvania, 57,963,038 gross tons; total, 87,083,134 gross tons. The spot value of the commercial product was as follows: anthracite, $65,520,216; bituminous and other coals, $72,453,797; total, $137,974,013. During the first six months of 1883, the output was: Pennsylvania anthracite, 14,010,767 gross tons; bituminous and all other coals, 30,000,000 gross tons; total, 44,010,767 gross tons. The spot value of the commercial product during the first half of 1883 was: Pennsylvania anthracite, $31,524,226; bituminous and other coals, $37,500,000; total, $69,024,226. Including the local consumption, etc., the total product in 1882 may be stated at 92,219,454 gross tons; namely, 31,358,264 tons of Pennsylvania anthracite, and 60,861,190 gross tons of other coals; and the value at the mines was: Pennsylvania anthracite, $70,556,094; bituminous coal, etc., $76,076,487; total, $146,632,581.

Iron.—The principal iron statistics for 1882 are as follows: Pig-iron made, 4,623,323 gross tons; spot value, $106,336,429. Iron ore mined, 9,000,000 gross tons; spot value, $32,400,000. Domestic iron ore consumed, 8,700,000 gross tons; spot value, $31,320,000. Imported iron ore consumed, 589,655 gross tons. Total iron ore consumed, 9,289,655 gross tons. Total spot value of all iron and steel in the first stage of manufacture, excluding all duplications, $171,336,429. Anthracite consumed in all iron and steel-works, including furnaces, 3,800,000 gross tons. Bituminous coal consumed in all iron and steel-works, including furnaces, 6,600,000 gross tons. Coke consumed in all iron and steel-works, including furnaces, 3,350,000 gross tons. Charcoal consumed in all iron and steel-works, including furnaces, 107,000.000 bushels. Limestone consumed as flux, 3,850,000 gross tons; spot value, $2,310,000.

For the first six months of 1883, the totals are as follows: Pig-iron made, 2,352,019 gross tons; spot value, $47,040,380. Iron ore mined (and consumed), 4,500,000 gross tons; spot value, $12,375,000. Imported iron ore consumed, 185,000 gross tons. Total iron ore consumed, 4,685,000 gross tons. Total spot value of all iron and steel in the first stage of manufacture, excluding all duplications, $71,000,000. Anthracite consumed in all iron and steel-works, including furnaces, 1,810,000 gross tons. Bituminous coal consumed in all iron and steel-works, including furnaces, 3,140,000 gross tons. Coke consumed in all iron and steel-works, including furnaces, 1,780,000 gross tons. Charcoal consumed in all iron and steel-works, including furnaces, 38,750,000 bushels. Limestone consumed as flux, 1,950,000 gross tons; spot value, $1,072,500.

Gold and Silver.—The Mint authorities furnish the following statistics for 1882: Gold, $32,500,000; silver, $46,800,000; total, $79,300,000; or an increase of $1,600,000 over the output in 1881. For the first six months of 1883, the product is estimated at $16,250,000 gold, $23,400,000 silver, and $39,650,000 total; the rate of production being assumed to be the same as in 1882.

Petroleum.—The production of crude petroleum in the oil-fields of Pennsylvania and New York in 1882 was 30,053,500 barrels of 42 gallons each, worth, at an average spot value of 78⅞ cents per barrel, $23,704,698. During the first six months of 1883, the yield was 11,291,663 barrels, worth, at an average spot value of $1.00⅛ per barrel, $11,305,778. In addition to the quantity above stated, California produced in 1882 about 70,000 barrels.

Copper.—The production of copper in 1882 was 91,646,232 pounds, worth, at an average value of 17¼ cents per pound in New York, $16,088,091. For the first half of 1883, the production is estimated at 58,000,000 pounds, worth, at an average price in New York of 14·65 cents per pound, $8,500,000. The spot value of the copper at the point of production is a matter which can not be stated with any accuracy; nor was any attempt made to ascertain the tons of copper ore mined. In 1882, 3,325,000 pounds of bluestone, worth $191,187, were made; and in the first half of 1883, the manufacture of bluestone is estimated at 1,662,500 pounds, worth $95,593.

Lead.—In 1882, 132,890 net tons of lead were produced, worth, at an average value of $95 per net ton on the Eastern seaboard, $12,624,550. For the first half of 1883, the production is estimated at 70,000 net tons, worth, at $90 per ton, $6,300,000. In this case, as with copper, it is impossible to state the average spot value of the lead, or the tons of lead ore mined. A very large proportion of the lead ore smelted is argentiferous, and is worked for its silver contents and not for the value of the lead. In the census year ended May 31st, 1880, the amount of white lead corroded was reported at 123,447,890 pounds, worth $8,770,699.

Zinc.—The production of metallic zinc in 1882 was 33,765 net tons, worth, at an average value of 5·4 cents per pound in New York, $3,646,620. The production during the first six months of 1883 is estimated at 18,000 net tons, worth, at an average value of 4⅝ cents per pound in New York, $1,665,000. In addition to the spelter and sheet-zinc made in this country, there is also a large manufacture of zinc oxide made directly from the ore. As in the case of copper and lead, it is impossible to fix an average spot value for the product, and the collection of statistics of zinc ore mined has not been attempted. In the census year 1880, the amount of zinc oxide manufactured, including that made from scrap-zinc, was reported at 20,121,761 pounds, worth $766,337.

Quicksilver.—In 1882, the production of quicksilver was 52,732 flasks (of 76½ pounds each = 4,033,998 pounds), worth, at an average price in

Digitized by Google

San Francisco of 36⅞ cents per pound, $1,487,537. During the first six months of 1883, the production was 22,740 flasks (= 1,739,610 pounds), worth, at an average price of 35½ cents per pound, $613,213. During the year 1882, 700,000 pounds of vermilion were made in the United States, having a total value of $315,000.

Nickel.—The production of pure grain nickel in 1882 was 277,034 pounds, worth, at $1.10 per pound, $304,737. There was also a production of 50 per cent copper-nickel alloy, containing 4582 pounds of nickel, worth $5040. The total nickel production was therefore 281,616 pounds, worth $309,777. The only nickel reduction-works in the United States were closed during the first half of 1883.

Cobalt.—The value of cobalt ores and matte for 1882 was about $15,000. The amount of cobalt oxide made was 11,653 pounds, worth $32,046.

Manganese.—The production of manganese ore in 1882 was 3500 gross tons, and the spot value at the mines, estimated at $15 per ton, was $52,500.

Chromium.—The production of chrome iron ore in 1882 was about 2500 net tons, worth, at an average price of $40 per ton in Baltimore, $100,000. The spot value can not be ascertained.

Tin.—A trifling amount of tin ore was mined in 1882 and the first half of 1883, and production of metallic tin began on a small scale toward the close of the latter period.

Antimony.—The production of metallic antimony, so far as ascertained, was 60 tons in 1882, worth about $12,000.

Building-Stone.—It is estimated that the value of the building-stone quarried in 1882 was $21,000,000.

Brick and Tile.—It is estimated that the total value of the brick and tile made in the United States in 1882 was $34,000,000.

Lime—There were 31,000,000 barrels (of 200 pounds each) made in 1882, having a total spot value of $21,700,000 at the kilns.

Cement.—The amount of artificial Portland cement made in 1882 was 85,000 barrels, worth, spot, $191,250. Of the cements manufactured from natural cement rock, there were 3,165,000 barrels made, worth, spot, $3,481,500. The total production of cement was 3,250,000 barrels, worth $3,672,750.

Clays.—Complete statistics of the quantity of fire and potter's clay mined in 1882 were not obtained. The value of the whiteware made was over $5,000,000.

Precious Stones.—The spot value of the precious stones found in 1882, before cutting, was between $10,000 and $15,000; after cutting, between $50,000 and $60,000.

Corundum.—It is estimated that 500 tons were mined in 1882, worth on an average only about $12.50 per ton, crude and unground; total, $6250. The value of the ground corundum manufactured during the same year was about $135,000.

Grindstones.—The value of the grindstones made from domestic rock in 1882 is estimated by leading dealers at $700,000.

Pumice-Stone.—There were 70 net tons quarried in 1882, worth about $1750.

Phosphates.—The production of washed phosphate rock in 1882 by the land mining companies of South Carolina was 191,305 gross tons; spot value, $1,147,830. By the river mining companies, 140,772 gross tons; spot value, $844,632. Total, 332,077 gross tons; spot value, $1,992,462.

Marls.—In New Jersey, 1,080,000 net tons of marl were dug in 1882. The average spot value at the pits is 50 cents per ton, making the total $540,000. There was a small yield of marls in some of the Southern States, the amount of which has not been ascertained.

Gypsum.—The most complete statistics for 1882 are those of the output of Michigan, namely, 37,821 net tons of land plaster and 135,655 barrels (of 300 pounds each) of stucco. The manufacture of plaster of Paris on the Atlantic seaboard was 525,000 barrels (of 250 pounds each), chiefly made, however, from Nova Scotia stone. Colorado produced 10,350 sacks of 100 pounds each. The production of California and some other States was not ascertained.

Salt.—The amount of salt made in 1882 was 6,412,373 barrels (of 280 pounds each = 1,795,464,440 pounds), having a spot value of $4,320,140. During the first six months of 1883, the production is estimated at 3,206,186 barrels (= 897,732,080 pounds), worth $2,160,070, the rate of production being assumed to be the same as in 1882.

Borax.—The production in 1882 was 4,236,291 pounds, having a spot value at the works of $338,903. For the first half of 1883, the output is estimated at 2,800,000 pounds, worth, spot, $224,000.

Sulphur.—Complete statistics were not obtained, The production in the census year was stated at 1,200,000 pounds, worth $21,000.

Barytes.—The amount of crude barytes mined in 1882 was 20,000 tons, worth at the point of production $160,000. The value of refined and ground barytes manufactured from the crude product above stated, was about $440,000.

Mica.—The quantity of merchantable mica mined in 1882 is estimated by leading dealers at 75,000 pounds, worth $250,000. The production is rapidly increasing.

Soapstone.—The amount quarried in 1882 is estimated at 6000 net tons, worth $90,000 at the quarries.

Quartz.—The amount of quartz mined in 1882 for glass-making and abrading purposes is estimated at 75,000 net tons,

Asbestos.—Amount mined in 1882, 1200 net tons, worth $36,000 at the point of production.

Graphite.—Amount mined in 1882, 425,000 pounds, worth, crude, at the point of production, $34,000. During the first six months of 1883, the production is estimated at 262,500 pounds, worth $21,000.

Carbonate of Soda.—Over 1,600,000 pounds were produced in 1882 from native deposits.

Asphaltum.—The production in 1882 was 3000 net tons, having a spot value of $10,500.

Alum.—No statistics. In the census year, the amount of manufactured artificial alum was reported at 39,217,725 pounds, worth $808,165.

Copperas.—The amount of copperas manufactured in 1882 is estimated at 15,000,000 pounds, worth $112,500.

The production of the following-named substances was insignificant: Apatite, arsenic, bismuth, infusorial earth, iridium, lithographic stone, nitrate of soda, ozokerite, platinum, strontia.

No reliable statistics were obtained of the following substances: Buhrstones, chalk, feldspar, fluor-spar, mineral paints, pyrites (for acid manufacture), sulphate of soda, talc (other than "soapstone").

None of the following substances is known to have been mined in 1882 or in the first half of 1883: Carbons, cryolite, rottenstone, wolfram.

Totals.—It is impossible to state the total mineral product in any form which shall not be open to just criticism. It is evident that the production statistics of such incongruous substances as iron ore, metallic gold and silver; the spot value of coal mined and the market value of metallic copper after having been transported hundreds of miles; the spot value of a crude substance like unground, unrefined barytes, and the value of a finished product like brick (in which the cost of manufacture is the leading item), such details can not well be taken as items in a general summary. The statistics have been compiled with a view to giving information on those points which are of most interest and utility, and are presented in the form usual in the several branches of trade statistics. The result is, that the values stated for the different products are necessarily taken at different stages of production or transportation, etc. Theoretically perfect statistics of mineral products would include, first of all, the actual net spot value of each substance in its crudest form, as taken from the earth; and yet for practical purposes such statistics would have little interest other than the fact that the items could be combined in a grand total in which each substance should be rated on a fairly even basis. The following groupings, therefore, are presented with a full realization of the incongruity of many of the items:

VALUES OF THE METALLIC PRODUCTS OF THE UNITED STATES IN 1882.

Pig-iron, spot value	$106,336,429
Silver, coining value	46,800,000
Gold, coining value	32,500,000
Copper, value at New York City	16,038,091
Lead, value at New York City	12,624,550
Zinc, value at New York City	3,646,620
Quicksilver, value at San Francisco	1,487,537
Nickel, value at Philadelphia	309,777
Antimony, value at San Francisco	12,000
Platinum, value at New York City	1,000
Total	$219,756,004

VALUES OF SOME OF THE NON-METALLIC PRODUCTS OF THE UNITED STATES IN 1882 (ALL SPOT VALUES, EXCEPT CHROME IRON ORE).

Bituminous coal, brown coal, lignite, and anthracite mined outside of Pennsylvania	$76,076,487
Pennsylvania anthracite	70,556,094
Crude petroleum	23,704,698
Lime	21,700,000
Building-stone	21,000,000
Salt	4,320,140
Cement	3,672,750
Limestone for iron flux	2,310,000
Phosphate rock	1,147,830
New Jersey marls	540,000
Crude borax	338,903
Mica	250,000
Crude barytes	160,000
Chrome iron ore, value at Baltimore	100,000
Soapstone	90,000
Manganese ore	52,500
Asbestos	36,000
Graphite	34,000
Sulphur	21,000
Cobalt ore and matte	15,000
Precious stones, uncut	12,500
Asphaltum	10,500
Corundum	6,250
Pumice-stone	1,750
Total	$226,156,402

RESUME OF THE VALUES OF THE METALLIC AND NON-METALLIC MINERAL SUBSTANCES PRODUCED IN THE UNITED STATES IN 1882.

Metals	$219,756,004
Mineral substances named in the foregoing table	226,156,402
	$445,912,406
Fire-clay, kaolin, potter's clay, common brick-clay, terra-cotta, limestone used as flux in copper and lead smelting, iron ore used as flux in lead smelting, pyrites (for acid-making), zinc white made directly from ore, marls (other than New Jersey), apatite, gypsum, tin ore, bismuth, arsenic, iridosmine, mill-buhrstone and stone for making grindstones, lithographic stone, talc (other than "soapstone"), quartz, feldspar, fluor-spar, terra alba, chalk, crude mineral paints, nitrate of soda, carbonate of soda, sulphate of soda, native alum, ozokerite, mineral soap strontia, etc.—certainly not less than	8,000,000
Grand total	$453,912,406

The grand total might be considerably reduced by substituting the value of the iron ore mined for that of the pig-iron made; by deducting the discount on silver; and by considering lime, salt, cement, borax, etc., as manufactures. It will also be remarked that the spot values of copper, lead, zinc, and chrome iron ore are much less than their respective values after transportation to market.

DYNAMITE STRUCK BY LIGHTNING.—The following well-authenticated case of the firing of a dynamite magazine is of interest: About a month ago, the company operating the salt mines at Avery's, or Petit Anse, Iberia Parish, La., received a large quantity of dynamite for blasting purposes. The same was stored in a magazine situated about four hundred yards from the works. Large trees were in close proximity. On Saturday, July 21st, a few minutes past twelve o'clock, a terrific storm burst on the island. Torrents of rain fell, and peal after peal of lightning rent the skies. The workmen had barely left and reached the boarding-house, situated at some distance from the works, when the lightning struck the magazine, and immediately there followed an awful explosion. For a few minutes, all seemed entirely paralyzed. Recovering, some rushed out to ascertain the cause. It was then discovered that the whole building in which was stored the explosive compound had disappeared, and in its place was left a yawning chasm fifteen or twenty feet deep by about one hundred feet in length. The trees surrounding were prostrated and shattered. One, 2½ feet in diameter, was carried by the immense power in the blast two hundred yards from where it previously stood. Every building on the island contiguous to the mines was shaken in a terrible manner, causing every glass door and window to part with its glass. The buildings containing the mills and machinery were much damaged, preventing access to the shaft for the time being. Eight box-cars, ready to be loaded, were entirely crushed in their upper part, the running gear remaining intact.

THE DIVINING-ROD.*

By Rossiter W. Raymond, Ph.D., New York City.

The extent to which the divining-rod is still used in this country for the detection of hidden treasure, mineral veins, or springs, is much greater than educated persons would be likely to suppose. For many years, wells have frequently been located by its aid in New England, where the belief is widely extended among the farmers that, in the hands of peculiarly gifted persons, this instrument possesses special virtue. Large numbers of the oil-wells of Pennsylvania have been bored at points designated by the so-called "oil-smellers." More than one adept with this instrument is practicing now in the Western mining region. I encountered, a few months ago, in Southern Colorado, a party of capitalists who were accompanied by such an expert, and whose purpose was to discover a mine, by his aid, and to buy the property thus made valuable. Still more recently, a paragraph in the Tombstone *Epitaph*, of Arizona, announced that a party of gentlemen from Chicago, whose names were given, had been scouring over the hills in the neighborhood of Tombstone, for more than a week, in company with an expert of Colorado, who had been employed to ascertain "with his well-known divining-rod" the localities of mineral wealth, and who had declared the existence of large bodies of ore in at least two places not yet developed. It is also reported, with what truth I do not know, that the Central Pacific and Southern Railroad companies have employed the divining-rod successfully in the discovery of water, and have located by this means their artesian wells in the desert. Last, but not least, a small book entitled *The Divining-Rod*, and published in Cleveland in 1876, contains an essay on this subject. read before the Civil Engineers' Club of the Northwest, at Chicago, in 1875, by Mr. Charles Latimer, a well-known engineer who has had charge of several important railroads, and who testifies in the most unqualified manner to the virtues of the divining-rod as a means of determining the position and the depth of subterranean water-courses, and claims to have discovered certain new and important laws of its operation, connecting if not identifying it with the force of electricity.

These circumstances, taken together with the fact that the "dowsers," or experts with the rod, still enjoy considerable local authority in Cornwall, and that believers in its efficacy may still be encountered among the German miners (although I think in that country the faith is more nearly extinct than elsewhere), certainly justify me in regarding this subject as one not solely of historical interest. Yet a consideration of its history and literature will throw important light upon the question, whether the phenomena which it has presented, and continues to present, are to be ranked under the head of self-delusion, deliberate deceit, or both; or, on the other hand, indicate, after all reasonable deductions for human error and credulity, a residuum of important scientific truth.

Before sketching the history of this instrument, it will be well to say a few words concerning its form, material, and use. Yet this is a work of no little difficulty. The immense literature of the divining-rod shows nothing more clearly than the boundless confusions and contradictions of its advocates and professors. Of the dozen different schools of practice, each is necessarily obliged to reject half of the asserted principles and certified facts put forward by the rest.

The most common divining-rod, perhaps, has always been a forked branch of witch-hazel in the shape of the letter Y. This wood may have been selected because it forks in such a way as to give two branches of equal size, or because of its supposed affinity for springs of water. But other woods, such as peach, ash, pitch-pine, and even metals, have been recommended at different times, and different professors of the art have also varied the shape of the rod, employing sometimes a straight twig with a small fork only at one end, or an elastic twig or whalebone without any fork. The dowsing-rod used by the expert mentioned in the Tombstone *Epitaph* is, I believe, an instrument made of two prongs of whalebone united in a stem which terminates in a case similar to a rifle cartridge. The contents of this case are a secret. (Similar cases, used in the middle ages, are said to have contained mercury.) This rod, like the ordinary forked hazel switches, is held in the two hands, each grasping the extremity of a prong, with the fingers closed not too tightly and the palms upward, the shank or stem of the rod being horizontal or vertical, or variously inclined, according to the principles of the practitioner. When carried in this manner by the operator, walking over the surface of the ground, the rod is said to turn or dip above treasure, mineral veins, springs, etc., but there is an elaborate and complicated science based upon the various degrees, directions, and force of this dipping. Unfortunately, the rules as determined by one or another celebrated operator have been found not to work for his rivals or successors, so that each authority lays down rules of its own. The straight rods were either balanced in various ways on one or both hands, or sprung bow-like between the two hands. The most peculiar rod described in ancient books was made of two pieces of wood, one of which was pointed and the other provided in the end with a socket. This rod, being delicately held, was said to indicate the presence of the object sought for by a peculiar revolution of the point in the socket.

An inquiry into the uses of such rods leads us at once to the history of our subject, in the study of which it will appear that divining-rods were first used in antiquity mainly or wholly for moral purposes; that, in the middle ages, their employment was for a long period confined to the discovery of material objects; that, toward the end of the seventeenth century, the moral use was again asserted: and that, in the eighteenth century, the divining-rod was relegated to the material sphere, and assumed the comparatively modest functions in the discharge of which it still lingers among us.

I would recommend to those who have not the means of an extended research the perusal of the book of Professor Fiske, of Harvard, on *Myths and Myth-Makers* (Boston, 1873), in the second essay of which, on *The Descent of Fire*, this subject is treated in the light of comparative mythology; also the work of Louis Figuier, *Histoire du Merveilleux dans les Temps Modernes* (Paris, 1860), half of the second volume of which is devoted to the divining-rod; and, finally, the book of Chevreul, *La Baguette Divinatoire* (Paris, 1853), which is a conclusive summary from the stand-point of modern science and experiment. I do not mention the work of Mr. Baring-Gould, *Curious Myths of the Middle Ages*, which Professor Fiske compliments with frequent quotations, for the simple reason that Mr. Baring-Gould's essay on the divining-rod is made up almost wholly of portions of Figuier's work, often translated *verbatim* and without credit. A brief, interesting, and impartial discussion of the divining-rod from the stand-point of the middle ages, together with a curious engraving illustrating its use, will be found in the well-known work of Agricola (*De Re Metallica*, Basle, 1546), published in the sixteenth century both in Latin and in German, copies of which, though not very common, are still to be met with in the antiquarian bookstores of Europe. I believe the library of the School of Mines of Columbia College contains a German copy. In the preparation of this paper, I have made use of the Latin edition, which is the only one in my possession. An excellent summary of the subject, containing many curious details, will be found also in Prof. Moritz Gaetzschmann's *Auf- und Untersuchung der Lagerstätten* (Freiberg, 1857). The Brooklyn Library contains a copy of a work entitled *Jacob's Rod: A Translation from the French of a Rare and Curious Work, A.D. 1693, on the Art of Finding Springs, Mines, and Minerals by Means of the Hazel Rod. To which is Appended Researches with Proofs of the Existence of a More Certain and Far Higher Faculty with Clear and Ample Instructions for Using it.* Published by the Translator: Thomas Walton, 13 Grafton street, Fitzroy Square, London. This book was published, I believe, in 1875. The title-page bears no date. The original French treatise, the translation of which occupies the first part, is probably the one entitled *La Verge de Jacob, ou l'Art de trouver les Trésors*, which Figuier (*Histoire*, etc., vol. ii., p. 257) speaks of as well-known to the adepts in occult sciences, and Chevreul (*La Baguette*, etc., p. 30) mentions as an example of the use of the term "Jacob's Rod," in those sciences, to signify a rod possessing marvelous properties. The origin of this signification will be found in Genesis 30. I suspect that neither Figuier nor Chevreul had seen this book: both of them fail to give either the name of the author or the date of publication, an omission especially noticeable in the case of Chevreul, who is usually both full and careful in his references. The translator gives the date as 1693, and names the author as M. Baritel. Of the fidelity of the translation I have no guaranty except internal evidence, from which I judge that it is honest rather than intelligent. This translator, Mr. Walton, is himself a mesmerist and electro-biologist, and declares his wife to be possessed of clairvoyant powers, of the exercise of which he believes the discovery of water, metals, etc., to be but one subdivision. The object of his translation and "addenda" is to connect the ancient phenomena of rhabdomancy, the observations and theories of Reichenbach, the fanciful speculations of Bulwer-Lytton, and numerous modern wonders (accounts of which he extracts from the *Spiritual Magazine*), and his own and his wife's alleged experience.

To the works above named I am indebted for nearly all the facts cited in this paper, and for many quotations made at second hand.

Professor Fiske, following Dr. Kuhn, whose treatise on the *Descent of Fire* was published in Berlin in 1859, traces the divining-rod to a wide-spread Aryan myth, connected with the forked lightning. Without going so far back, we may find in written history many evidences of the use of the rod, not only as a symbol of earthly power, but also as the instrument of supernatural effects, and particularly of divination. It will be remembered that the Egyptian sorcerers confronted by Moses carried rods, as Moses and Aaron also did. The prophet Hosea denounces the use of rods for divination by the Jews (Hosea 4:2). According to another prophet (Ezekiel 21:26), the king of Babylon consulted rods or arrows to decide his course. The Scythians, Persians, and Medes used them. Herodotus says that the Scythians detected perjurers by means of rods. The word *Rhabdomancy*, originated by the Greeks, shows that they practiced this art; and the magic power of the rods of Minerva, Circe, and Hermes or Mercury, is familiar to classical students. The *Lituus* of the Romans, with which the augurs divined, was apparently an arched rod. Cicero, who had himself been an augur, says in his treatise on divination, that he does not see how two augurs, meeting in the street, could look each other in the face without laughing. At the end of the first book of this treatise, he quotes a couplet from the old Latin poet Ennius, representing a person from whom a diviner had demanded a fee as replying to this demand. "I will pay you out of the treasures which you enable me to find." This ancient joke, by the way, has been adopted in all seriousness by the "oil-smellers" of Pennsylvania, who, as I am informed, are accustomed to locate oil-wells on precisely this condition, receiving nothing if the well proves unsuccessful, and fifty dollars if oil is struck.

Marco Polo reports the use of rods or arrows for divination throughout the Orient, and a later traveler describes it among the Turks. Tacitus says that the ancient Germans used for this purpose branches of fruit-trees. One of their tribes, the Frisians, employed rods in church to detect murderers. Finally, if we may trust Gonsalez de Mendoza, the Chinese, who seem to have had every thing before any body else, used pieces of wood for divination.

Thus we perceive that the application of the divining-rod in historical antiquity was mainly or wholly moral; that is, it was employed to detect guilt, decide future events, advise courses of action, etc., etc. There are but two passages which have been quoted to prove its use for physical purposes: one from Ctesias (*apud Phot. Bibl. Cod.*), who speaks of a rod of the wood *Parebus*, which attracted gold, silver, other metals, stones, and several other things: the other from Cicero (*De Officiis*, lib. i.), who says, "If we could obtain with the so-called divine rod every thing pertaining to food and clothing" (*ad victum cultumque*), etc.

On the other hand, the silence of many authors is significant, as Chevreul has pointed out. Varro does not mention the use of the rod for the discovery of subterranean waters or metals. Vitruvius, discussing the means of discovering springs, says nothing of it. Pliny, in Book xxx. of his Natural History, omits it from his enumeration of magical arts and methods, and in Book xxxi., describing (after Vitruvius) the means of discovering springs, and in Book xxxiii., describing explorations for metals, is equally silent concerning it. Columella, Palladius, and, in the sixth century, Cassiodorus, are likewise dumb, though the latter in one of his epistles (*Theodoric*, liii.) extols the utility of the pro-

fessional water-discoverers. Even as late as 1569, a book printed in Orleans (*L'Art et Science de trouver les Eaux et Fontaines cachées sous Terre autrement que par les Moyens vulgaires des Agriculteurs et Architectes*, par Jacques Besson, Dauphinois, mathématicien), contains no allusion to the rod. It is a curious circumstance that this work emanated from Dauphiny, the home, a century later, of the most famous diviners and water-discoverers.

But the alchemistic literature brings the physical uses of the divining-rod to the front. The first mention is usually credited to the *Novum Testamentum* of Basil Valentin, a Benedictine monk and hermeneutic philosopher of the fifteenth century. But it must be remembered that the existence, even, of this man is not beyond doubt. It is attested by Gadenus (*Historia Erfordiensis*, 1675), who says that Basil was living at the convent of St. Peter's at Erfurth in 1413. Yet the *Testamentum* was actually first printed at the beginning of the seventeenth century, though manuscript copies had been circulated earlier. Of these, Chevreul possesses one (a French translation) dated 1651, and from it quotes the famous passage according to which, at the time of the writer, the divining-rod was worn in the belt or the hat, and was used to discover metals. Basil describes seven varieties of the rod, according to its different motions.

Whatever its antiquity, the use of the rod to discover hidden treasure or metallic ore became general in Germany, and was extended thence through Flanders, England, Sweden, France, Italy, and Spain, before the end of the seventeenth century. It must be remembered that in those days the practice of burying money and plate was universal. A rod that would discover buried treasure only would, at the present time, be of comparatively little value. We know well enough where the large masses of gold and silver are piled. It is not ignorance, but bolts and bars, that prevent our getting at them; and a large class of the diviners of the middle ages would be obliged, if they lived to-day and practiced their profession, to become burglars or cashiers.

The scientific explanation of the divining-rod at this period, like the scientific explanation of nearly all facts in chemistry and physics, was "affinity," a word under which was concealed a little science together with a vast amount of ignorance and superstition. Philip Melanchthon (1497–1560), the friend of Luther, adopted this theory to explain the effects of the divining-rod. We must confess that, in an age when the attraction of the magnet for iron and of electrified amber for light bodies was known, but not understood, there was no necessary absurdity in supposing that similar phenomena might be exhibited by other classes of substances. And this natural presumption, joined with the inherent credulity of ignorance and the tendency to generalize upon imperfect data, caused a very general acceptance of the alleged operations of the divining-rod as true, and consequently the promulgation of crude quasi-scientific theories to account for it. On the other hand, it must be remembered that the belief in demoniac agencies was still active and all-pervading, so that when facts could not be scientifically explained, they were at once referred to witchcraft or to the devil directly. So long as the discussion remained within the field of science, it was conducted with courage and candor; but when it entered the demoniac domain, the boldest philosopher, unless he were willing to sell his soul to Satan, became dumb. This may explain the attitude of the great Agricola (*De Re Metallica*, lib. ii.) a keen observer and wise reasoner, who, after saying that the alleged virtues of the divining-rod are subject to much dispute, and stating both sides of the dispute with admirable clearness, demolishes in a few words the supposed analogies of magnetism and electricity, but declares that, if the divining-rod derives any power from spells and incantations, that is a matter neither permissible nor agreeable for him to discuss. He proceeds, moreover, to assert, as the general result of experience in his time, that the professors of the divining-rod, though they sometimes succeed in discovering veins, quite as frequently fail, and have to dig like other people if they wish to find any thing. Wherefore, he advises the respectable and sober miner to study the indications of nature, and then dig at once, without further fooling. In a quaint woodcut which accompanies this passage, a miner is represented in the background as cutting his hazel twig; while another in the foreground is proceeding with it in due form for the discovery of the mine; and (whether in sarcasm or not, I do not undertake to say) at the very point to which the latter is steering, two of Agricola's "good and sober" miners have already found ore by the homely process of digging.

Paracelsus (1495–1541) condemns in his works, as uncertain, illusory, and unlawful, the use of the rod. His disciples did not uniformly agree with this view. Goclenius, author of *Essays on the Virtue of Plants and the Unguent of Arms*, believes in the efficacy of the rod, and does not condemn its use. Libavius, author of the *Syntagma Arcanorum Chimicorum* (died 1616) believed in it from experience, and explains its action by sympathetic affinity. This theory, already announced by Melanchthon, was also held by his son-in-law Peucer, by Porta (*Magia Naturalis*, 1569, lib. xx., cap. viii.), by Keckermann (1573–1609, *Systemata Physica*, lib. i., cap. viii.), by the author of one of the discourses published with those of Maiolus, Bishop of Volturara (1614), and by Michael Mayer, the prolific author of alchemistic allegory (*Verum inventum, hoc est Munera Germaniæ*, cap. iv.), who, describing the invention of gunpowder in Germany and the use of hazel-charcoal in its original manufacture, mentions the sympathy which hazel-wood has for metals, and its consequent employment in the form of the divining-rod.

On the other hand, the Jesuit father Laurentius Forer (*Viridarium Philosophicum seu Disputationes de Selectis in Philosophiâ Materiis*, 1624) condemns the use of the rod as a superstitious practice. We must distinguish therefore three different views of the question: two of which accepted the efficacy of the rod as proved, and ascribed it respectively to a physical property of the rod, and to demoniac agency, while the third discredited the alleged facts, and pronounced the practice to be a superstition.

A fourth view was indeed advanced, according to which the operator, as well as the rod, was the recipient of a divinely-given faculty. It was no doubt with the purpose of removing the odium attached to dealings with the Evil One that the professors of this science, particularly in Germany, surrounded it with ceremonies and formulas of a highly pious character. It is true that the rules sometimes prescribed for the cutting of the twig partook largely of heathen sorcery and astrology. They were indeed, to some extent, unconscious reminiscences of the old Scandinavian, and even of the Aryan, mythology. But this was atoned for when the rod was duly Christianized by baptism, being laid for this purpose in the bed with a newly baptized child, by whose Christian name it was afterward addressed. The following formula, cited by Gaetzschmann, may serve as an example: "In the name of the Father, and of the Son, and of the Holy Ghost, I adjure thee, Augusta Carolina, that thou tell me, so pure and true as Mary the Virgin was, who bore our Lord Jesus Christ, how many fathoms is it from here to the ore?" In this case, the rod was expected to reply by dipping a certain number of times, corresponding to the number of fathoms.

Such devices, however, were not everywhere successful in diverting from the practitioners of this occult science the evil name of sorcery. A striking and pathetic instance is furnished in the seventeenth century by the history of the Baron and Baroness Beausoleil. The baron, born in Brabant, devoted himself to mineralogy and mining, and became, undoubtedly, one of the foremost mine-engineers of his time. He visited and studied the mines of Germany, Hungary, Bohemia, Tyrol, Silesia, Moravia, Poland, Sweden, Italy, Spain, Scotland, England, and France. The emperors Rudolph and Matthias appointed him counselor and commissary-general of the mines of Hungary. The Archduke Leopold made him director of the mines of Tyrol and Trent. The dukes of Bavaria, Neuburg, and Cleves gave him the same title. Finally, the pope did the same for all the papal states. He appears to have amassed from these various employments a considerable fortune.

In 1600, he was engaged by the comptroller-general of the mines of France to open mines in Languedoc and some other provinces, and in 1626 this commission was still further extended. During this period, he met and married his wife, who devoted herself with enthusiasm to his profession, studying and traveling extensively with him in Germany, Italy, Sweden, and perhaps Spain. They even made a voyage to the shores of the new world. In 1627, their house was robbed under the legal forms of search on the charge of sorcery preferred by a local official. Their loss was estimated at one hundred thousand crowns. They easily obtained acquittal of the charge; but it is an instructive commentary on the justice of the time that they never were able to recover their property. They went to Hungary, but returned to France in 1632 under a new commission from Louis XIII. In this year, the baroness, who was an accomplished author, published an account of one hundred and fifty mines already discovered in France, and of some medicinal springs. They expended, in further explorations, nearly the whole of their fortune; but were unable, in the face of their jealous rivals and enemies, to obtain from the government the grants which had been promised them, and by means of which they expected to reimburse themselves. Finally, the baroness published a work, addressed to Richelieu, and entitled *The Restitution of Pluto* (reprinted at Paris in 1779), in which, with eloquent indignation, she declared the deserts of her husband and herself, and asserted their right to the rewards promised them, urging the cardinal-minister at the same time, by every consideration of the glory and greatness of France, to encourage the development of its mineral resources. Unfortunately, in this work she furnished new material for the slanderous accusation of sorcery. In magnifying the art of discovering mines and springs, and the skill required for this purpose, she gives a description of the means employed, showing that these hidden treasures are to be detected—

1. By digging, which is the least important way;
2. By the herbs and plants which grow above springs of water;
3. By the taste of the waters which flow from them;
4. By the vapors which arise from them at sunrise;
5. By the use of sixteen scientific instruments and of seven rods (the seven rods of Basil Valentin), connected with the seven planets, etc.

The first four means were undoubtedly real and really employed. Under the fifth head, we have an illustration of what is so common in the alchemistic and other mediæval writers, namely, the covering of the facts of nature and the methods of investigation with assumed mystery, to hide them from the vulgar. So long as the baron and baroness were spending their own money for the good of the state, they were permitted to go on, and even received complimentary notices from time to time, which, indeed, could not be withheld from persons of such eminent reputation. But when they became troublesome in their demands for more substantial favors and came in collision with the "rings" which infested the kingdom, the charges of sorcery renewed against them furnished a convenient pretext for putting them out of the way. Richelieu may even have supposed that he was behaving in this case with lenity, since instead of having them burned to death, as he did with another sorcerer of the same period, he only put the baron in the Bastille (1642) and his wife in Vincennes, where they soon (about 1645) died in destitution and misery, victims not so much of the superstition as of the corruption of the times.

It will be noted that the treatise of the baroness did not claim for the divining-rod any moral virtue. What the Beausoleils appear to have done for this instrument was to bring forward its use in the discovery of springs as well as metals. The literature of that period seems to ignore in the main any powers of the rod in prophecies or moral discrimination.

(TO BE CONTINUED.)

A MINER'S RECKLESSNESS.—John Sykoski, the miner's laborer burned at Plymouth and removed to the hospital, is dead. The death of this man was scarcely less than suicide. If his act was not suicidal in intention, it was as bald a piece of stupidity as one ever encounters in mining operations. He had been up nearly all the night before playing pool, and without any need for powder, went to a covered box, removed the lid, took out a can of powder, unscrewed the cork and somehow brought the contents in contact with the flame of his lamp. The only theory that can be gleaned from the facts is, that he mistook a powder-can for an oil-can and poured the powder into his burning lamp. But the oil and the powder are kept separate, and in boxes at least sixty feet apart, and the man had been working five months in that chamber and knew all about it. He must have been stupid and dazed by drink and loss of sleep. He was burned too badly to explain how the accident happened.

THE FLOW OF WATER THROUGH PIPES.*

By Hamilton Smith, Jr., M. Am. Soc. C.E.

The following table gives the results of 88 experiments as to the discharge of water through circular pipes, ranging from 4 feet to ½ inch in diameter, and with velocities varying from 20 feet to ¼th of a foot per second. The pipes were of rolled and cast-iron, glass, and wood; their interior surfaces varied from the almost perfect smoothness of glass to the roughness of old iron, much incrusted by the continued action of soft water. Of the 88 experiments given, 71 were made by the writer of this paper, and 17 have been selected from standard authorities, for the purpose of more extended comparison.

Experiments Nos. 1 to 15, inclusive, etc., were made at North Bloomfield, California, with three pipes laid side by side across a ravine about 100 feet lower than the pen-stock. They were made of single-riveted No. 14 sheet-iron; the rivet-heads had worn pretty smooth, and no deduction for them was made in computing the areas. The pipes had been carefully coated when first laid with a mixture of coal-tar and asphaltum, and their interior surfaces at the time of these measurements were quite smooth. They were put together in slightly conical joints, the greatest variation in diameter being about ¼ of an inch. The main joints were some 20 feet in length, put together stove-pipe fashion, as is always done in the California hydraulic mines. The various heads were obtained by adding to the length of the pipes at their outlets. The heads, lengths, and mean diameters are given with exactness. The amount of discharge was measured by running the water over an iron weir, the coefficients of whose discharge, with varying depths, had been carefully determined by absolute measurement, but at another point, and under conditions not exactly similar. This gauging was done with all the care practicable, the hight of the water being measured with a Boyden hook gauge, reading to ·001 of an inch. The limit of possible error in these experiments is probably not over 2 per cent. Experiments Nos. 6 and 7, however, are somewhat unreliable, owing to the stoppage of a stone passing through the pipe. The coefficient of contraction is assumed at 1 in these pipes, as each of them had a short funnel-shaped inlet, which was included in the measurement of their lengths. In Nos. 1, 6, and 10, the discharge was into a pool of water at the outlet-box; in the other 12, the discharge was into the air. There were two angles in the line of these pipes, one of 9 degrees and the other of 11 degrees; for the remainder of the distance, they were nearly straight; in the computations, no deduction was made for these bends.

No. 17 is based chiefly upon data given to the writer by the engineers who had the hydraulic works of the Spring Valley Mining Company in Butte County, California, in charge. It may be incidentally observed that this pipe was laid in 1870, and has remained in perfect condition ever since its construction. It is made of double-riveted sheet-iron, having a thickness of ⅜ths of an inch at the point of greatest pressure, where the actual head is 887 feet. The maximum tensile strain on the iron is 17·549 lbs. per square inch. The rivet-heads for one half the length of the pipe no doubt perceptibly retarded the flow of water. Round stones weighing about 25 pounds passed through the pipe with a velocity of 9·0 feet per second, while the computed velocity of the water was 10·78 feet.

No. 18 was a single-riveted sheet-iron pipe, with the interior surface worn quite smooth, and with joints put together stove-pipe fashion. The mean diameter, head, and length are given with exactness; the discharge was measured through a series of apertures, no great accuracy being practicable. The limit or possible error in this case may be as much as 4 per cent.

Nos. 22 to 28, inclusive, are the early experiments of Couplet, and seem to be reliable. The authorities for Nos. 16, 19 to 21, and 29 to 34, inclusive, are given in a note. Nos. 29 and 30, being the Rochester supply main of two different diameters, show an apparently excessive discharge. This was stated to have been directly measured by the filling of a reservoir of known size. Nos. 31 and 32 are given as illustrations of extremely rough surfaces. Mr. Kirkwood states that in No. 32—the Jersey City main—the pipe was comparatively new, which makes the very low coefficient of discharge quite remarkable.

Nos. 35 to 87, inclusive, were made by the writer at New Almaden, California. All these experiments were with straight pipes, and were made with considerable accuracy. The mean diameters were computed by the weight of water contained in the pipes, taken by the sum of the weights in the several joints, which varied slightly from the mean of the end diameters as directly measured. The discharge was determined by filling a tank of known size. The iron gas-pipes were joined by their usual couplings. The ends of the glass pipes were smoothly ground, and a water-tight joint made by an outside rubber band. The wooden pipe was joined by usual plug couplings. The funnel mouth-piece for the inch gas-pipe was 10¼ inches long, with a mouth 6¼ inches in diameter; the funnel for the inch glass pipe was 3¼ inches long, with mouth 5 inches in diameter. These mouth-pieces were not included in the given lengths of the pipes. Nos. 35 to 52, inclusive, were made with the same pipe, which was new and in good order; it was first used without a mouth-piece, then with a mouth-piece, and afterward the pipe was dipped in a bath of boiling coal-tar and asphaltum, giving it a very smooth coating. Nos. 53 to 56, inclusive, were with a shorter section of the same pipe. The pipe used in Nos. 57 to 63, inclusive, has been in use for several years, was rather rusty, and was slightly incrusted by the action of lime-water. The method of obtaining the diameter—by the quantity of water contained—gave the exact size of the pipe at the time of the experiments. The glass pipes used were new and unscratched, of French manufacture, and somewhat conical. There were twelve joints of the inch pipe, which were nearly evenly matched in diameter at the junctions; the largest diameter was ·0875′, and the smallest, ·0717′. The measuring tank held 15·2 cubic feet, and the times were determined to ¼th of a second.

No. 88 was with a new inverted siphon of double-riveted sheet-iron pipe, with a pressure of about 800 feet at the lowest point, with a maximum tensile strain of 16,500 pounds per square inch, and with most of the joints made by sleeves with lead packing. It was coated with the usual mixture of coal-tar and asphaltum. No deduction was made for rivet-heads, which for over one half the length doubtless formed noteworthy obstructions, as the pipe was of comparatively small diameter—17 inches. The mean diameter, head, and length are given with exactness. The discharge was measured first by the flow over a weir, and afterward through standard apertures; these determinations were not as satisfactory as could have been desired, although three separate trials gave nearly identical results. The chances are, that the discharge was slightly underestimated. A noticeable feature in this experiment is the fact that blocks of wood, loaded to a specific gravity of 1·05, passed through it with a velocity of 20·9 feet per second, while the calculated velocity of the water was only 20·13 feet. In several of the other experiments, similar tests always showed a less speed of the blocks of wood or stone than that of the water, which is readily to be accounted for by the blocks striking the rivet-heads. In No. 18, there was no noteworthy difference between the velocity of unloaded wooden blocks and that of rough stones.

In all the experiments made by the writer, the actual or total head was either the difference in elevation between the surface of the water in the pen-stock and that in the outlet-tank, or the difference between the water in the pen-stock and the center of the escaping jet, where the pipe discharged into the air. Experiments 35 to 87, inclusive, were made under the latter condition.

The standard of measure used was that of the United States Coast Survey. The temperature of the water in Nos. 35 to 87 was about 65 degrees Fahr. In the other experiments, from 50 to 55 degrees Fahr.

The writer here desires to express his obligations to the North Bloomfield Gravel Mining Company, and to Mr. J. B. Randol, manager of the Quicksilver Company, for the facilities afforded by them in pursuing these investigations.

These 88 experiments have all been reduced to the simple formula:

$$v = m\left(\frac{d\,h'}{l}\right)^{1/2}$$

Where v = velocity in English feet per second.
d = mean diameter.
l = length.
h' = effective head.
m = variable co-efficient.

This is identical with the usual form:

$$v = n\,(rs)^{1/2};\ 2\,m = n.$$

The effective head h' was derived from the total head h, as follows, c being coefficient of contraction at entrance:

$$h - h' = \frac{v^2}{2\,gc^2}.$$

The comparative results of these experiments when shown by graphic delineations, the coefficient m being used as abscissæ, and the velocities in feet per second as ordinates, prove that the value of m varies with:

First. The character of the interior or wetted surface, being very low with small, rough pipes.

Second. It increases with the velocity with smooth pipes, but this increase is slight with small, rough pipes.

Third. It increases with the diameter, which is to some extent a sequence of the first proposition.

It may be observed, in connection with the second proposition, that the coefficient m will be infinitesimal, with an infinitesimal velocity. In fact, with a minutely appreciable head, m will probably still remain infinitesimal, owing to the viscosity of the water.

The value of m at first increases very rapidly with the increase in velocity; this increment gradually diminishes until, with high velocities, m becomes nearly constant.

Mr. I. T. Fanning, in his *Treatise on Water Supply Engineering*, arrives at the same three general conclusions as those here given.

In the larger pipes, one of which discharged fifty cubic feet per second, it was not practicable to measure the water directly, on account of the large outlay which would have been requisite to build measuring-tanks. Any indirect measurements of flowing water, either over weirs or through standard apertures, are always unsatisfactory, as the slightest change in the conditions will affect the accuracy of the results. A discordance, however, is to be noted in these experiments (35 to 87), which is the low value of m in the pipe 16⅜ feet long, when compared with its value in the pipe 60 feet long (49 to 52) of the same diameter. This discordance leads to the belief that the usual correction for loss of head, due to imparting velocity to the water $\left(\text{loss of such head} = \frac{v^2}{2g}\right)$ should be modified. The discrepancy can hardly be caused by the deduction for contraction at the orifice, as experiments 35 to 41 and 42 to 48 give practically identical curves, and where first a considerable correction was given for the contraction, and afterward, with the same pipe, a very slight correction for the same cause. An extended series of experiments with pipes of the same size, but of widely differing lengths, made with proper care, is much to be desired, in order to definitely settle this point.

It may be remarked that some 150 additional experiments, made by standard authorities, have been carefully tabulated for purposes of comparison with the 88 here given. Their results were often contradictory, although generally confirming the correctness of the three general propositions before stated. The importance to the hydraulic engineer of this question is best appreciated by the statement that the experiments given show a variation in the value of m from 33 to 67. The first 87 had been tabulated by the writer before he designed and built the Texas Creek pipe—No. 88. The expected value of m for this siphon was then fixed at 66·5, this value being deduced from the preceding tests. The trial test of this pipe showed a value of 65·56, which, as stated before, is probably slightly less than its real value.

* A paper read before the American Society of Civil Engineers.

ON THE DEVELOPMENT OF THE WATER-PRESSURE ENGINES IN THE FREIBERG MINING DISTRICT.*

By Gustav Hahn, Obergruna.

(WITH SUPPLEMENT.)

Though more than seven hundred years old, the Freiberg silver mining industry has shown its vitality even under adverse circumstances. It owes its development not only to the richness of the ores, but to the extensive utilization of cheap water-power for hoisting and pumping. The oldest of this class of machinery, partially still at work, consists of large water-wheels, and, in spite of the large head of the water, they were almost exclusively used until 1820, a number of them often being placed below one another, in order to utilize the power. It is true that Mende built engines of a different type as early as 1768, but none of them is now in use, nor did they have any important bearing upon the development of the water-pressure engine in the Freiberg District, which must be dated from 1820, when Brendel rebuilt an engine put up in the Reicher Bergsegen mine to utilize a head of 287·75 feet. His design attracted a good deal of attention. It was put into the Alte Mordgrube, and had a head of 328·7 feet, a 16·72-inch cylinder, an 8·36-feet stroke, and, making four strokes per minute, showed an efficiency of 70 per cent. Its work encouraged the building of water-pressure engines in the district, and since then there have been built to date thirty water-pressure engines for pumping and hoisting purposes.

The Freiberg system for obtaining water-power is exceedingly elaborate. Eleven collecting-ponds are distributed near the Bohemian frontier, connected by ditches and tunnels. They have a capacity of 176,800 million cubic feet of water, and furnish the mines with from 1600 to 2175 gallons a second. The total length of the ditches and supply tunnels is 257,322 feet, paid for by the mines. For this water conducted into the mines, an outlet had to be provided, and thus a large number of tunnels were driven, the latest being the famous Rothschoenberg, which, with branches, is 166,572 feet long, and, according to locality, decreases the lift of the pumps and increases the available head of water by from 308 to 498 feet.

The water-power thus created, during so long a time and at so great an outlay, had to be utilized by the mechanical engineers of the Freiberg mines by water-pressure engines, and their principal aim has been to improve the valve-gear. One of the principal drawbacks of the valve-gear is, that it admits too great a velocity of the water when entering the cylinder, and that the cutting off of the pressure-water takes place too suddenly, so that strong concussions are brought about. Braunsdorf tried to get over the trouble by using an auxiliary valve-piston, while Schwannkrug tried double pistons.

It is important, to secure quiet working of a water-pressure engine, to have the descending rods move slowly, so that the masses moving with an accelerated velocity toward the end of the stroke can be stopped toward the end of the stroke without shocks. This is partly accomplished by throttling the water flowing from the main cylinder, and partly by an hydraulic counterpoise.

The engines shown on the accompanying supplement show the principal variations adopted in the Freiberg mines. Figures 1 to 4 exhibit the engine designed by Gustav Hahn for the Reiche Zeche mine. It was to be put in on the level of the Rothschoenberg tunnel, to be supplied with 6½ gallons a second of power water with a head of 404·7 feet, and making four 6·56 foot strokes per minute, lift the water from the fifth level, 337·3 feet below the tunnel and the water obtained in sinking the shaft down to the 6th level. The engine has a piston a, with cross-head moving in the working cylinder b, the latter being mounted on a base-plate resting on two iron beams. The regulating mechanism consists of two regulator cylinders, the main regulator cylinder D and the auxiliary regulator cylinder E, the regulator shaft w, upon which are mounted the levers k for the up-stroke, and k' for the down-stroke, moved by s' and s^2. By the oscillating movement of the shaft w, which is imparted to it alternately by k and k', the lever h and the auxiliary regulating piston attached to it are moved up and down. The auxiliary regulator cylinder E is connected by a pipe with the supply-pipe F, and may be cut off by the cock E'. The water entering through this pipe flows into the auxiliary regulator cylinder between the pistons δ and δ', and when these two pistons occupy their highest position, it is conducted through the channel u into the main regulator cylinder. The motive water enters the main regulator cylinder D through the pipe F F and the cock g, between the piston β and the piston α, and escapes to the tunnel through the piston α'. This water may be throttled by means of a valve at H, thus retarding the down-stroke of the driving-piston. In the position shown, the engine is just beginning its up-stroke, s^2 has, through the medium of the levers k and h, depressed the auxiliary regulator piston to its lowest point, the space above the piston β is connected through u and γ with the discharge-pipe, and therefore, as the surface of β is larger than that of α, the piston β will move to its highest position; α and α' follow this movement, α opening the supply-valve, admitting motive water into the driving-cylinder while α' has simultaneously closed the exhaust-valve. When the driving-piston has reached its highest point, the roller s' has lifted the lever K' to its highest point, and with it the piston δ δ'. The motive water flows from F through E and u over the piston β, pressing it downward, closing α' and opening α. In order to prevent the piston β from suddenly attaining its highest position under the great pressure to which it is subjected in the beginning, when the supply-valve is not yet closed, it is important to throttle the exhaust motive water by the valve γ,' so that by flowing off slowly it permits only a slow following of the regulator piston.

Figures 5 to 7 show a water-pressure engine designed by Herr Braunsdorf for the Rudolf shaft at Marienberg. It has a working cylinder with only one regulator piston α and the auxiliary piston α'. The arrangement of the auxiliary regulator cylinder is shown in the drawing. The lever a is moved up and down by b and b', and this movement is transmitted to the auxiliary regulator piston. The engine has a head of water of 183·7 feet, a supply of motive water of 25 gallons a second, a stroke of 7·69 feet, and makes 4·6 strokes a minute. The velocity of the water entering the engine is 5·58 feet, but nevertheless it works quietly. This engine is also supplied with a throttle for the motive water at c, for the exhaust at d and at g.

The third engine, Fig. 8, is one designed by Herr Bornemann for the Zenith mine at Oberschoena. It differs from the two others in that the driving-piston is not a plunger, and that it works with an hydraulic counterpoise, the engine being mounted below the level of the tunnel, so that it has a counter column of 6·56 feet, an arrangement justified by the fact that the engine must on its up-stroke run a lifting set and on its down-stroke need only counterbalance a weak wrought-iron pump-rod. The arrangement of the main regulator cylinder with the two double pistons, the throttle-valves a, d, and D, is similar to that of the other machines.

* A paper read before the Saxony Section of the German Society of Engineers.

UTILIZING ASHES.

Mr. J. A. Shinn, of Pittsburg, has been for some time experimenting with, and has obtained a patent for, the use of ashes in making mortar. In the city of New York about 700,000 cubic yards of ashes are annually produced, which require to be carted to the docks, loaded upon boats, and taken to the lower bay in order to dispose of them, at a cost to the city of over $400,000.

In addition to this, the large manufacturers dispose of their own ashes in like manner at their own cost. The fine portion of the ashes of domestic production, that is, stoves, grates, ranges, and heaters, is capable of being converted, with a small proportion of lime, into a mortar having a tensile strength of from four to five times that of common sand and lime mortar, or about 80 pounds per square inch, one month old, to sand mortar 20 pounds at the same age, and, when mixed as béton, gives a tensile strength of 140 pounds and a crushing strength of over 1100 pounds per square inch. one month old.

It will thus be seen that, by utilizing the ashes for mortar, a large part of the expense of removal could be saved, together with the whole cost of procuring sand for that purpose, and at the same time a very superior article of mortar be produced.

In consequence of the small quantity of lime required (10 per cent), it would be necessary to mix the mortar by machinery at a mill and deliver it ready for use. This practice prevails to a great extent in European cities on account of the superiority of milled over hand-made mortar. Ash-mortar has the additional advantages of resisting the action of water as soon as it has set (in from two to three days), and also the combined action of fire and water, the quantity of lime being so small and the chemical union with the ash so complete, that the application of heat does not produce free oxide of lime, as in the case of sand-mortar, and consequently does not swell when water is applied to the heated mortar. The weight of ash-mortar is about one half that of sand-mortar when both are dry, and it works soft and smooth. Ash-mortar forms, when set, a silicate of lime and alumina, and hardens uniformly throughout, like cement; while sand-mortar, when set, is but an imperfect carbonate of lime, the sand furnishing but the nucleus around which the carbonate forms.

Ashes made under steam boilers, or in other fires where a high degree of heat is maintained, are not suitable for mortar, owing to the chemical change which takes place in the fire; the finest part of such ash, that found behind the bridge-wall of the boiler, being found to be of the same nature as the coarse clinker, having no special affinity for lime, and being only fit for combination with cement or plaster.

THE TRANSVAAL GOLD-FIELDS.

The last mail from South Africa brings intelligence of a very satisfactory character from the gold-fields now opening up in the Transvaal. Various reports of the richness of the deposits in the neighborhood of Lydenburg have been received from time to time, notwithstanding efforts on the part of those who were first in the field, and endeavoring to obtain concessions, to keep the facts secret. There are now, however, several mining engineers in the district, surveying on the part of capitalists in Cape Town and elsewhere, and several of the newspapers have sent special correspondents to the fields, who all concur in giving the most satisfactory accounts of the quantities of gold lying ready to be worked. In many cases, the precious metal lies close to the surface, the loose soil requiring only to be dug up and worked. In others, rich quartz-veins extend in an unbroken line for two or three miles. On a slope of the Spitzkop farm, two claims which have been quietly worked for the last twelve months have yielded £6000 worth of gold; and the prospectus states that the deeper they go the richer the ground becomes. There is no hard quartz to break, the reef having become rotten or disintegrated by the action of the weather. Nuggets of twenty ounces and thirty ounces in weight have been picked up in the rubbish. Two diggers actually threw away lumps of quartz, which they have not the necessary appliances for crushing, but which have been proved to contain four ounces of gold to the ton. In consequence of these and similar facts, shares in claims owned by Cape Town adventurers have risen in value from £24 to £50 each. At another claim adjoining, a month's wash-up produced 420 ounces of gold, worth £1470. At a third claim, known as Gwynne Owen's concession, on the water-fall property, the ground is even richer, there being large deposits of alluvial soil, consisting in some places of nearly half pure gold. On Berlin, Lisbon, and Hermansburg farms, old Portuguese workings, forgotten for centuries, have been discovered, partly buried beneath overgrowing vegetation, but intersected with rotten reefs, yielding from 5 to 20 ounces of gold per ton. It would seem probable that these workings were abandoned from the same cause which has driven recent explorers back from the country farther north, in Matabele land and Eersteling fields—namely, the hostility of the natives, who prevented several parties from taking away specimens of gold. When proper machinery is erected on these new gold-fields, their value will be increased many times, the diggers at present employed there being satisfied to use merely the pick and shovel, and to wash the stuff in rude appliances through which a large quantity of gold is lost. In one case, a corresponident of the *Friend of the Free State* reports that "quartz is thrown away when actually gold is discernible to the naked eye."

PENNSYLVANIA BITUMINOUS COAL AND CANADIAN IRON ORE.

The Buffalo correspondent of *Coal* has the following important communication in this week's number, and it is well worthy of consideration: Now here is some "brain-food" for your readers. Perhaps it may be conducive to their pecuniary advantage, and if so, I hope they will financially remember your correspondent. Closely connected with the coal production in the counties of Clearfield, Elk, Jefferson, and Indiana, Pennsylvania, which lie south of Buffalo from one to two hundred miles, are the iron and especially the steel industries, likely at no very distant day to become the leading industries of all that region. The carbonates of iron of the coal measures, which were formerly used in the smelting furnaces in some of these counties, are inferior, both in quality and yield, to the primitive ores so abundant in the Lake Superior regions. It takes on an average three tons of the carbonates to produce one ton of not very good iron, while one ton and a half of the northwestern ore will yield one ton of the best steel and iron; the same quantity of Canadian primitive ore, found near Kingston, produces the same quantity of iron; in both cases, the fuel required is in proportion to the weight of the ore. These primitive ores can be brought here in vessels and taken into the coal regions for use in the iron-works as return loading for coal cars, while the returning ore-carrying vessels can carry back coal, which will always be wanted in the cold climates north and west of us. It seems clear that these rich iron ores will supersede the lean ores of the coal measures for the reasons above given; their use will tend to the advantage of the coal trade. This makes it proper, while treating of coal, to speak of its kindred industries, steel and iron-making. By the by, it is a fact which has a bearing upon our railroad and navigation interests that vast amounts of the excellent iron ores of Elba, Spain, Algiers, and other regions in the old world are brought to Johnstown, Pa., for use in the extensive Cambria Iron and Steel-Works, to the entire exclusion of the local ores of that vicinity. If we should have direct railroad lines to that point from Buffalo, there seems to be no good reason why the ores of Lake Superior should not be sent there and fully supply their works with all the needed qualities.

FLAMELESS COMBUSTION.

Two papers have recently been published on this subject, which are of considerable interest. One by Mr. Fletcher, in *Dingler's Polytechnisches Journal*, 246, 293–5, states that, in experimenting with gas and air-burners, the author found that the smaller the flame produced, the greater was the heating effect which could be obtained from the consumption of a given quantity of gas. This result led him to reduce the flame as much as possible, and ultimately it was proved that under the most favorable conditions the flame would disappear entirely. If, for instance, a ball of iron wire be heated in the flame of a gas blow-pipe, and the supply of air be gradually increased, the jet of flame will become smaller and the temperature will gradually rise. Then, if after the ball has been heated, the gas tube be pinched for an instant so as to extinguish the flame, it will be found that there is a sudden increase of heat, and that the iron will be melted. A similar increase of heat during flameless combustion is shown if a lump of fire-clay be substituted for the iron wire, and petroleum vapor may be used in the place of coal-gas. The author's experiments are still in their infancy; it is hoped, however, that they will be the means of effectually utilizing much of the heat at present wasted. These experiments of Mr. Fletcher's have been repeated by Mr. Fischer—*Dingler's Polytechnisches Journal*. 247, 32–35—with the view of investigating the combustion products. For this purpose, iron wire was wound around the end of a thin clay pipe, so that a ball from 6 to 8 cm. thick was produced. This was treated as suggested by Fletcher, and while the ball was at its most intense heat, a sample of gas was withdrawn from the interior, the gas being drawn through the clay pipe and examined over mercury. The experiments corresponding to samples of gas I. and II. were made with the ordinary gas pressure; in experiment III., the pressure was increased, while the pressure in experiment IV. was still greater. The ball in experiment II. was made of very thin wire; in experiments I. and III., the wire was one mm. in thickness; and in experiment IV., the ball consisted of a mixture of both wires:

	CO_2	CO	CH_4	H	O	N
I	5·11	....	.....	....	6·26	88·63
II	5·03	....	.....	....	3·34	91·63
III	6·60	....	.....	....	4·98	88·42
IV	7·72	1·08	traces	0·32	traces	90·88

The composition of the gas corresponds with that of the gaseous mixture at the point of the flame of a blow-pipe or Bunsen burner; the small proportion of oxygen, however, shows that part of it is retained by the iron; moreover, it was found that, when thin wire was used, one half of the fused mass consisted of ferrosoferric oxide. Referring to the practical application of flameless combustion, the author considers that it is not available for solid fuel.

FURNACE, MILL, AND FACTORY.

It is stated, as a result of the strike of the workmen in the rolling-mills at South Chicago, where 1800 men are usually employed, that the management has decided to shut down for an indefinite period.

The double shift at the Bethlehem steel mills continues, and on the 1st the fires in the puddle mill were started. A large body of union men was addressed in the morning by Vice-President Lee and William Jones, of Pittsburg. Money is distributed liberally among the men who are loyal to the union.

The preliminary steps have been taken to establish at Newport News, Va., extensive fertilizer and chemical works, the latter for the production of sulphuric acid from iron pyrites, which abound along the line of the Chesapeake & Ohio Railroad, the supply being, it is said, inexhaustible and rich in sulphur. The effect of these works will be to reduce the price of fertilizers by cheapening the cost of the acid, which is one of their principal constituents.

The Harrison Boiler-Works, Philadelphia, Pa., have been having tests made of their boiler by Professor Morton, of the Stevens Institute of Technology. In his preliminary report, Professor Morton informs the company that it can safely guarantee an evaporation of nine pounds of water into high-pressure steam for each pound of coal burned, and that under all conditions the steam is completely dry, showing a slight amount of superheat. In regard to capacity as compared with rated size, a 50-horse-power boiler developed (on a basis of thirty pounds of water) from 64 to 75 horse-power, varying with the kind of coal used. Neither of the coals used showed less than 16 per cent of refuse. The evaporation during the capacity tests above referred to was, per pound of coal, from 9·25 to 9·93 pounds, and per pound of combustible from 11·04 to 12·5 pounds of water. The feed-water was heated to 212 degrees, and the pressure under which the water was evaporated was about 70 pounds per square inch. In a test with a blower, the 50 horse-power boiler developed 137 horse-power.

The new plate mill of the Springfield Iron Company, which was recently started, is thus described by the Illinois *State Journal*:

The outfit of new machinery consists of a Porter-Allen automatic cut-off engine, with a cylinder 44 by 48 inches, and a fly-wheel 27 feet in diameter, and weighing something over 30 tons. This engine is calculated to make over 100 revolutions per minute. Then comes the train of three-high plate rolls, which are 31 and 20 inches in diameter and 110 inches long. They are furnished with massive housings, pinions, spindles, and coupling-boxes, and also with a pair of small steam-engines, whose only office is to work the screws which raise and lower the rolls. Accompanying the rolls are two massive tilting-tables, each 30 feet long, with driven rollers, which receive the steel as it comes from the furnace and send it backward and forward through the rolls until the work on it is complete. The operation of these feeding-tables is very complete as well as interesting. By their use, very heavy plates can be rolled, and with a very great saving of labor. When the plate is finished, it is to be pushed off the end of one of these tables endwise on to a cooling-bed. This consists of a series of cast-iron boxes, filled with water to keep them cool, and furnished with loosely-fitting covers. The plates rest on these covers and become perfectly straight and smooth while cooling and before removal. This bed is over 40 feet long, and arranged to accommodate a very long plate. When the plates are cool, they are raked off this bed sidewise by hydraulic machinery on to a bed, where they can be allowed to accumulate if necessary. From this they are taken by a hydraulic crane, and either distributed on the floor preparatory to marking for shearing, or they are taken directly to the shears, to be trimmed and cut into shapes desired by the customers for whom they are intended. These shears are a curiosity. They weigh over 70 tons, are driven by an engine big enough to run a flouring-mill, and will take off at a single bite a piece of steel 100 inches long and 1¼ inches thick. When the plate is sheared, another hydraulic crane takes it up and swings it on to the cars on which it is to be shipped, a railroad track having been laid directly into the new mill for that purpose.

The following concerns were the contractors for the different parts of the new plant: The Southwark Foundry and Machine Company, of Philadelphia, furnished the engine; the rolls and train were made by A. Garrison & Co., of Pittsburg. Mackintosh, Hemphill & Co., also of Pittsburg, furnished the feeding-tables; and Morgan, Williams & Co., of Alliance, O., the cooling-bed, cranes, and shears.

The capacity of the Siemens and Pernot furnaces is 500 tons of steel ingots per week without forcing. They are charged into two very large Siemens gas heating furnaces. After heating, they are drawn out by hydraulic machinery and deposited on the feeding-tables before referred to, and the process follows as already described. The weight of these ingots will generally be about a ton, but some have been made of two tons, and sometimes even up to 6000 pounds. The thickness of the ingot is from 9 to 12 inches, according to its weight, and its width is 20 inches. When the plate is finished, its thickness has been reduced to about one quarter of an inch. The width is any thing desired up to 110 inches, and the length as desired up to 30 feet.

GENERAL MINING

ARIZONA.

BIG BUG DISTRICT.

Gus F. Stoddard, of Stoddard, has sold to Marcius de Leon an interest in the Hold Fast, Bonanza, Fair, Wide Awake, and several other valuable mining claims in the Big Bug and Agua Fria districts, the consideration being $8000. These claims, so far as developed, are remarkable for their richness, and possess every indication of true fissure-veins, and will undoubtedly prove rich bullion-producing properties, as they are situated in a section of country noted for its mineral wealth.

COCHISE COUNTY.

CAVE.—From Bisbee, it is reported that in this mine, on the eastern slope of Copper Queen Hill, a large cave containing considerable quantities of copper ore has been discovered.

GRAHAM COUNTY.

ARIZONA COPPER COMPANY.—The Clifton *Clarion* says: In the report of Messrs. Williamson and Rankine, the Scottish engineers who visited Clifton last month, we find the following in regard to three groups of mines belonging to this company:

QUEEN MINES.

In our first report, we touched lightly upon the ore found in these mines, as the works had not progressed to any advanced stage. Since then, a large amount of work has been executed, and the Queen mines have now developed into a valuable property. The vein to which we referred as being irregular has proved to be a true fissure-vein, which has been drifted into by upper and lower levels, disclosing a large quantity of high-grade ore. The width of the vein runs from two to three feet, and an output of over thirty tons per day may now be regularly had for many months at small cost, even supposing nothing more should be disclosed. Of course, mines must be continued in the strike of the ore and the greater depths. The ore, to all appearances, continues to improve as the mine deepens, the strike of the vein being indeed traceable on the surface to depths below that to which it has already been opened out. The mines have now been connected with the private railroad by a self-acting incline, 1500 feet in length, of excellent construction, as all the inclines are, so that the ores may be readily sent to the works.

CORONADO MINES.

A large amount of work has been executed at these mines. The day tunnel has been drifted nearly through the crest of the hill, having advanced a total length of about 1400 feet, measured from both ends, which will reach connection within from forty to fifty yards. A greater length of it is in barren ground than we anticipated; but that is partly accounted for by the fact that latterly the object has been to push it through in the ground where the material was softest. Some exploring side mines and shafts have been also driven, but these have not been generally so successful in finding ore as we should have liked. On the other hand, additional shafts and short mines farther down the hill, on the Boulder and Horse Shoe claims, have disclosed rich and valuable bodies of ore, so that altogether we see no reason to depart from the opinion we formerly expressed regarding the value of this group. A considerable quantity of ore has been accumulated at various dumps, and there will be no difficulty in sending away and maintaining a daily output of thirty or forty tons.

METCALF MINES.

The work done at these mines has been of considerable extent. A self-acting incline, 1200 feet in length, has been completed to these mines, and a proportion of the ore now used is regularly sent to the smelters. There is a quantity of ore, estimated at 800 tons, on the dump, and we see no difficulty in obtaining a regular supply of over 40 tons per day, at a moderate cost per ton, from these

Digitized by Google

mines; but we have not the requisite data for offering an opinion as to the permanence of the output.

The railroad for connecting the works at Clifton with the public railroad at Lordsburg is making rapid strides toward completion. At the time of our inspection, forty-two miles, next Lordsburg, were completed, which we traveled over by train. Some delay had occurred in the delivery of rails; but assuming these to be sent regularly forward, as we understand will be the case, the works otherwise are so far advanced that the line may be completed to within about six miles of Clifton in a few weeks. The facilities that will be given by the railroad will tend very much to the economical and regular working of the whole properties of the company.

SILVER KING.—The Pinal *Drill* says: The men are working on the 700-foot level, extending the sill-floor in the breast north and east, and also stoping on the second, third, fourth, fifth, and sixth floors of the same level, extending the sill-floor of the 500-foot level still, preparatory to stoping. All work has been stopped on the 800-foot level until the air improves with our summer rains, and which one good shower will accomplish. We have had no rain at the King, but plenty at Pinal. The blower is set, only waiting for pipes, so as to be independent of seasons, and permit the workers to have good air, whatever the weather. About 100 men are employed.

YANKEE BOY.—A big strike is reported in the Yankee Boy, situated a little north of the Silver King. The Yankee Boy has lain still for some time on account of too much water in the shaft, but now, since relieved of that inconvenience, the gravel has been passed, and large deposits of rich ore in the main lead have been found.

SILVER DISTRICT.

CLIP.—Only ten months ago, this mine was considered a prospect, nothing more; but Hiram Shipman and A. G. Hubbard saw a fortune in the claim, and secured a bond on it, and G. W. Bowers became interested with them in the property. Immediately after securing the option of the property, a thorough development of the ledge was made, and the mine was purchased. A road was built to meet the county road, and the grading for the mill at the river begun. Every thing on the property was done in an economical, systematic manner. The ledge was cut at various places, another shaft sunk, and careful samples taken of all the ore in sight. The Clip mine is about seven miles from the Colorado, in Silver District, and distant from Silent five miles north. The ledge is fully 125 feet wide in places on the surface, and can be distinctly traced beyond its side-lines on to the Alberta mine. The croppings and ledge-matter cut by the tunnel are 150 feet high and give good No. 1 ore, ranging from 18 to 27 feet between walls, all pay. This rich body of ore is known to extend fully 300 feet in length, and how much more can only be determined by further explorations. In addition to this great mass of ore uncovered, there is a quantity of $20 rock, enough to run a mill for years. Rock going $20 per ton, in this mine, can be worked to a profit, as the ore is easily mined, scarcely any powder being used. Four men can take down fifty tons of mineral per day. The $20 rock, however, is only a reserve, as there is sufficient ore of higher grade to keep the mill busy for two years to come. A cable road conveys the car loaded with rock to the ore-bin from the mine.

TOMBSTONE DISTRICT.

TOMBSTONE.—Under date of the 22d ult., Prof. John A. Church has sent the following report to this company:

We made a good strike in the West Side fourth level yesterday, and to-day it showed some very rich galena, value not known, but probably from 60 to 70 per cent lead, and I presume above 500 ounces of silver per ton. This kind of ore was found only toward evening, and I shall not see it until to-morrow. Aside from its value, the find is important, because it occupies a block of ground which was barren on the third level.

As you know, we have just south of the No. 3 shaft, on the third level, a ∧ shaped stope, the ground dipping both ways from an apex, and carrying ore on both stopes. On the third level, there is no ore between the two stopes of the ∧, but the new strike is between them. It dips southward, parallel with No. 2 winze from the third level, which has gone down to the fourth on ore, and is about 35 feet distant there from the new strike. I suppose this new body of ore is developed from 4 to 6 feet thick.

Northward, the fourth level has passed one ore-streak about two feet thick, and this morning appeared to be approaching another. In this direction, the inclined portion of No. 1 winze has been carried about half-way down to the fourth level; and if it continues as it has every appearance of doing, should reach the fourth about 120 feet north of the shaft. From present appearances, the large ore-bodies which stretch for 80 feet along the third level near shaft No. 3 will cover 200 feet on the fourth level. These stopes on the third are yielding largely and continually and of high-grade ore. They are already the thickest we have had in the West Side, and are getting larger every day. We have not yet carried them to the second level, though the ore is known to rise to that point. I have frequently spoken of the fact that on the third level the ore lies in sheets crossing the line of the vein and ending on the west in the main vein and on the east in a branch from it. One of these sheets measures 34 feet in length, from 2 to 4 feet in thickness, and, so far, has been carried 75 feet high. Within the ∧ shaped mass we have had, so far, three of these sheets dipping northward, and two dipping southward; and if they all have the same length, we shall get twice the usual quantity of ore out of a given length of vein. In many ways, this portion of the mine is looking even much better than I expected to see it. Hitherto, our attention has been given principally to the branch vein, which was much larger than its parent; but lately we have been stoping in the latter, and it seems to be as large as the average in this mine, and yields very high-grade ore. It looked small simply by comparison. Though it is somewhat early to venture an opinion, I suppose the fourth level will yield twice as much ore as the third, and the grade can not fail to be an improvement.

At the south end, No. 1 shaft will be connected down to the third level within two days. I shall then timber it and drift southward with strong hopes of adding from 200 to 300 feet to our ore-ground. Northward of the No. 3 shaft and the large stopes near it, we are not doing so well. The drift is 120 feet from the shaft, but the vein is small and the rock black and blocky. The presence of ore in the survey shaft, 400 feet north of No. 3, is our only encouragement there; but these conditions are likely to improve on the fourth level.

No. 3 shaft is going down, and is thirty feet below the fourth level. We are likely to reach the fifth level some time before the fourth is fairly opened, and our work will then be a long way ahead of our needs.

No. 7 on the Tough Nut looks as well as ever, but is not worked hard.

At the mill, our bullion shipments are $1000 ahead of last month, and the little interregnum of low-grade ore of which I spoke in my last letter is passed. Yesterday's amalgam was 150 pounds more than we have had before.

The furnace is running well; but we have got to a part of our old pile of concentrates that was made from Gird tailings at a time when the ore carried little lead, and our shipments have fallen off in weight, while they have increased in value per ton.

The new concentrating mill has part of its machinery in place. Mr. Handley is working vigorously, and when every thing is finished, our work will be done on the best methods and our whole plant be the most perfect in America.

We took 500 tons of manganese from the Stonewall last month; and as that mine is now closed, I shall increase the force at the Lucky Cuss somewhat. That property is still looking well. We are working in two places and know of four others where manganese can be had.

The new prospect found on the Tribute proves to be small—only four inches thick; but the ore seems to be high in grade. It is worked by the discoverers on tribute at present.

The rainy season proves to be violent only in wind. The prospect is, that our dam will hold.

CALIFORNIA.

THE CALICO DISTRICT.

BLACKFOOT.—Work is progressing on this claim with favorable results. An incline-shaft has been sunk twenty-four feet, in about the center of an open cut some fifty feet in length. It is estimated that the body of ore that is opening is at least 100 feet wide, and it extends to the bottom of the shaft. How extensive the deposit of ore is, can not be definitely determined, but, judging from the work already accomplished, a great many thousand dollars will be extracted before it is exhausted. Ore has been stoped out twenty feet on both sides of the shaft. About ten tons have been shipped to San Francisco, and there are about fifteen tons of ore on the dumps, including 113 sacks. Another milling will be made shortly.

SNOW BIRD.—A few days ago, work on the Snow Bird was suspended, but operations will be resumed within a month. This mine, although it was not so rich as was first expected, has been yielding very good returns in bullion to its owners. A number of rich pockets of ore on the surface have been exhausted apparently, but new places have been opened that have yielded well. Recently, in a cut along a vein which is now fifteen feet in length, seven tons of ore were taken from a place broken up by one blast of powder. This ore was taken to the Oriental mill, twenty-one sacks of which assayed 400 ounces, and the rest from 75 to 219 ounces. The last shipment of ore to the Alhambra mill averaged very high—the returns from the first grade of the same, $520 to the ton and the second grade, $239. The cut mentioned above is running in a body of ore about fifty feet in length, and twelve or fifteen feet in width. The men are down over six feet, and there is ore on the bottom. This body of ore will no doubt yield many thousand dollars before it is exhausted.

INYO COUNTY.

MONTEZUMA.—About ten days ago, a new body of ore, measuring many tons, was opened on the Montezuma mine. It is of fine grade, and gives promise of being as extensive as the body heretofore opened and developed. The new find is situated about 300 feet below the present dump, and dips into the hill as if it ran into and formed a part of the deposit from which the old body of ore is an output. It is exceedingly suggestive in that it indicates the presence of a very extensive deposit throughout the entire hill. Explorations at this point will be vigorously prosecuted, and it is confidently expected that the results will largely increase the extent and value of the property. It is the opinion of several leading experts who have recently examined this property that the Montezuma is a large and permanent mine, and that the wonderful product of Cerro Gordo will be here rivaled. On Monday last, the Furnace site was located and surveyed; a side-track laid out, and at the present time, the grading and track-laying are carried forward to connect the site with the main railroad track. The material and lumber for the furnace are *en route*, and will all be on the ground by the first of next week, when work will be begun and prosecuted in earnest. The mine and furnace are owned by the Owens River Mining and Smelting Company. The station and grounds have been named Elma, in honor of the daughter of Mr. W. P. Miller, superintendent of the company.

NEVADA COUNTY.

The county board of equalization at Nevada City has made reductions in the assessments of hydraulic mining properties aggregating nearly $200,000. These reductions were confined to the North Bloomfield, Eureka Lake, and Milton companies. The assessment on the Manzanita Company was increased $16,000. The quartz mines were allowed to stand as assessed.

The suit of Hill & Hill *vs.* the Eureka Lake & Yuba Canal Consolidated, which was an ejectment to recover certain property valued in the neighborhood of $50,000, has been compromised and dismissed from the Superior Court, where it has so long been on trial. Defendant pays to plaintiffs the sum of $5500.

CANADA.

LAKE SUPERIOR.

SILVER ISLET.—A rich strike is reported from Silver Islet, the miners having struck a rich pocket of silver in the 1160-foot level. These pockets of silver have been phenomenal in this mine, and, whenever found, have always been very productive in silver. The news had the effect to send up the price of stock in the Boston market, where it is principally held, from four to eight dollars per share.

COLORADO.

Governor Grant has appointed John T. McNeil, of Clear Creek County, State Coal Mine Inspector, in accordance with the recommendations of the Board of Examiners, which has been sitting at the State House. The applicants were Mr. McNeil, Thomas J. Williams, and Mr. Dwight, all of Coal Creek; John Nichols, of Golden; Henry Brigs, of Denver; and Daniel Rees, of Erie. The examinations were very rigid, and all contestants are satisfied with the manner in which they were conducted.

CLEAR CREEK COUNTY.

The *Register-Call* prints the following statistics of production for the first six months of this year:

Smelting ore sold	$488,175.00
Gold bullion	463,9[illegible]0.80
Tailings sold	219,240.00
Gold from United Gregory	35,000.00
Ore sent directly to smelters and sampling-works in Denver	50,000.00
Total	$1,256,315.80

The total production of Gilpin County for 1882 was $2,006,516, and a glance at the figures of the first half of 1883 shows an increase of $250,000. The outlook for the ensuing six months of the present year is such as to warrant the prediction that the amount of smelting ore and mill-dirt that will be marketed and treated will equal if not exceed that portion of the year reviewed.

The Union Reduction Company has its new mill and concentrator about completed, and will start the new machinery within a week or ten days. Ore is received from all parts of the district, and by the time the mill starts, there will be a sufficient amount of ore on hand to keep it going for some time. All the ore received thus far is high grade.

CYCLOPS.—The main shaft has been sunk 92 feet, and timbered in a substantial manner; plats have been cut and levels inaugurated at the respective depths of 375 and 440 feet. The present depth of the main shaft is 450 feet. In addition to these improvements, 200 feet of winzes have been sunk, 800 feet of levels driven, and 75 fathoms of ground stoped out, which produced 275 tons of ore which has been sold to the smelters, containing 24,680 ounces of silver, having a currency valuation of over $26,000. In addition to that sold, a large amount of ore, suitable for concentrating, has accumulated on the dumps. The management has had but one object in view, that of developing the property thoroughly and sytematically. The above statement is the best attestation of that fact. The main shaft will continue down to the depth of 800 feet, stations

Digitized by Google

and levels adopted at convenient intervals below the 440-foot levels. The mine has more than paid for all dead-work. Over the main shaft is a conveniently-arranged shaft and ore-house, and a powerful plant of machinery.

GUNNISON COUNTY.

The Rose & Reed concentrator has shut down until stamps can be put in. It was discovered that the rolls would not effectually crush the ore, and it was deemed advisable to waste no further time with them, but to set about immediately putting in stamps. Operations will probably begin in two or three weeks.

LAKE COUNTY.

The Harrison Reduction-Works, at Leadville, will close down temporarily on account of scarcity of ore.

The Esty & Sampson concentrating-mill is running on material from Catalpa waste-dump, and also slums and tailings from a lot of refuse material known as the "Seventh street dump." The stuff had all been run through an imperfect concentrating device once before; but Mr. Esty states that the mill is doing very well with it.

ADLAIDE.—The lessees of Adlaide and Terrible mines, according to all reports, have struck the largest bonanza yet opened by lessees in this district. The mine now shows a breast of ore nearly one hundred feet long and of exceptional strength. Conservative estimates place the resources at 5000 tons, which will net at least $100,000. So far this month, the mine has shipped at least twenty thousand dollars' worth of ore. The shipments average thirty tons a day of ore having an average value of forty-five dollars per ton. Deducting royalty, smelting charges and cost of mining, the ore leaves the lessees about twenty dollars per ton, and it is said that the average daily income is at least five hundred dollars. The ore-body was opened near the Adlaide No. 2 shaft. The lessees are Messrs. E. R. Holden, A. Chanute, Charles Taylor, and L. P. Feustman.

ARGENT.—The mining reporter of the *Herald* has visited the Vining mine, on Rock Hill, the property of the Argent Mining Company, of Philadelphia. The mine is working under the management of Mr. J. L. Loomis, and for eighteen months past has proved a limited but regular producer. The shaft on the property has a depth of about 340 feet, passing through boulder wash and porphyry for 300 feet, and penetrating the underlying limestone about 40 feet. The underground workings show quite extended developments radiating on the line of contact, in all directions from the shaft. The limestone shows numerous and heavy rolls, and frequently irregular elevations. The favorable appearance of the cap-rock, as well as the underlying limestone, would indicate a generous contact and fine ore. An inspection of the mine, however, soon corrects this erroneous opinion, and shows the visitor that Mr. Loomis has had much to contend with in keeping the mine in a producing condition. The ore-bodies where found are generally weak and irregular. The mineral seems to be located on the highest points of the lime, and occurs in thin sheets, ranging from two to twelve inches in thickness. Occasionally, the mineral fills cavities and subordinate sags in the bedding-floor, but these are generally quite limited in their extent. The prospects for opening larger resources are favorable, and a great deal of judicious exploration-work is going on. The resources of the mine, while not large, are nevertheless sufficient to guarantee a regular production for a considerable time in the future, and permit the mine to make continuous shipment while prospect work is carried on. The ore is a gray sand carbonate, running well in both silver and lead.

AUSTRALIA.—Upon Little Ellen Hill is situate the Australia, a property that has come into recent prominence, and which has made phenomenal strides during the present season. The operators have a six-foot body of carbonate ore, from which they are shipping between fifteen and twenty tons per day that nets them about $30 per ton. There is a shaft eighty feet deep upon it, from which an incline runs west over 30 feet.

BRADSHAW.—The principal workings of this mine, on Printer Boy Hill, has been a tunnel, which has been worked to a distance of 800 feet. A two-foot vein of gold ore has been struck, an assay of which returns the handsome amount of six ounces in gold. The ore is sacked and shipments will soon begin.

CATALPA.—The Catalpa and Crescent mines show very little ore at present, and appearances would indicate that the mines are about worked out. The ground has been thoroughly prospected, and after this month no more money will be expended in exploration-work. The lessees have also nearly exhausted their available resources. The Catalpa mine shows large masses of fine iron ore, but the mineral can not be extracted at a profit at the present price of iron ore.

CHRYSOLITE.—A contract has been closed within the past few days which will give Leadville a new twenty-stamp mill as soon as it can be erected. For some time past, Messrs. N. H. Cone and Eben Smith have been negotiating with the Chrysolite Company for the large dumps of low-grade iron ore on its premises. The officers of the company, after considering the matter thoroughly, finally advised giving the contract, and last week the board of directors of the Chrysolite Company authorized its officers to close negotiations with Messrs. Cone and Smith, on a contract whose term of existence is nominally placed at forty-five years. The ores embraced in their contract are the large dumps of iron and mineralized vein-matter scattered over the premises of the Chrysolite consolidated mines, and estimated to contain about 40,000 tons of milling ore. The mineral is the same as that on which Mr. Clark made numerous experiments in concentrating, etc. After thoroughly testing the ore, it was found impossible to do any thing with it, except to run it through a crushing and amalgamating mill. The dumps were next measured and sampled, and their contents ascertained, which were found to be only thirty pounds of lead to the ton and not silver enough to pay for smelting. A profit of from two to three dollars per ton was, however, estimated as possible, by treating the ore under stamps. These results were reported to the company, and the directory seeming rather averse to making any heavy expenditure for a stamp-mill, and assuming the consequent responsibility, decided to let the present contractors assume the risks and put up a mill. The contract calls for the ores now on the dump and such ore as may in the future be taken out, that can be milled at a profit, but is of too low a value to make a profitable smelting ore, and will be paid for at a stipulated price per ton. The milling material now out and that which it is expected will be extracted in pursuing work in the mine, is calculated to keep a twenty-stamp mill continuously employed for the next three years, and will give the Chrysolite Company from $75,000 to $100,000. The company also furnishes the mill with water privileges, a mill-site, and a right of way for tramways from the different dumps to the mill. Regarding the mill, Mr. Cone said it would be at least twenty stamps, and fully equipped with the latest improved machinery now in use in silver mills. He has been in correspondence with manufacturers of the Boss continuous amalgamating process, and thought very favorably of it, but wished to satisfy himself on a few points before making a final decision.

GOLD LEAF.—The lessees of the Gold Leaf, belonging to the Humboldt Mining Company, are at present sacking and shipping considerable high-grade ore. The recent strikes in the Gold Leaf carry with them a great deal of importance, as they are the first strikes of any consequence on the south slope of Carbonate Hill.

PILOT.—In this property, which is located on the California Gulch slope of Printer Boy Hill, a new strike of exceptional magnitude has been made by the lessees, including Messrs. F. X. O'Brien, Phil Golding, and Sport Goris. It was at a distance of 400 feet in the tunnel on this property and 175 feet from the surface that a winze was started. The object of this policy was to connect with an uprise that had been run from the Bradshaw, which was abandoned on account of water, when the lessees concluded to open the ground from above. They had sunk but fifteen feet, when they came upon a crevice of matter that is heavily impregnated with horn-silver. The vein is small, but there is every reason to believe that this is simply a streamer from a large body of mineral

SAN JUAN COUNTY.

The San Juan *Herald* contains a long description of a number of claims in Dry Gulch, about a mile and a half above Delmino. Carbonates of copper and galena carrying silver have been found.

The Stahl concentrator is pushed to completion as rapid as possible, and Professor Stahl intends having the mill in operation by the fifteenth of August. There are hundreds of tons of ore on the dump of the Sampson and other mines awaiting the starting of the mill.

Seven concentration-works will be running in the Upper Animas country by the 15th of August.

BEN FRANKLIN.—This mine is located about one mile up the right-hand Fork of Eureka Gulch, almost on a level piece of ground, and the open cut where the rich mineral was found is where the trail to the Sunnyside mine crosses it. Two years ago, Mr. Howard sold it to Messrs. W. E. Webb and W. A. Whiton for $1000. These parties did nothing with it, except patent it, until this spring, when they set a few men at work, making an open cut and shaft within a few feet of the creek. In sinking this shaft 14 feet, they took out nothing but solid lead ore, and at the depth of 13 feet they struck between three and four feet of rich antimonial silver and gray copper, from which assays ran from 500 to 2000 ounces in silver. Water beginning to come in rapidly, work had to be abandoned in the shaft. At this point, the mountain rises about one hundred feet at an angle of thirty-five degrees, and the croppings extend over this rise and show the lead ore on the surface. Men were set to work blasting and quarrying out the mineral on this side-hill. The mineral is known to be 30 feet wide, and how much wider is not known. Forty feet below the cut, the width of the mineral exposed is 75 feet. A cross-cut tunnel, now in 65 feet, is running to cut the vein at a depth of about 100 feet after running some thirty feet more.

HIGHLAND MARY.—The main tunnel has reached a depth of 2680 feet, being 2375 feet below the surface of Innes Mountain; and when the tunnel has been completed to the Bald Eagle fissure, it will be 3450 feet below the surface of the vein. The tunnel is now going ahead with unusual prosperity, and an average of 75 feet each week made with the Ingersoll drills. We were informed that about 2200 feet would have yet to be run before any remuneration could be expected from the mine, when they expect to cut the Bald Eagle lode.

NATIONAL BELLE.—The parties in negotiation for this property are Mackey, of Nevada, the silver king, and Senator Osbiston, who have a price of $800,000 now at their disposal. They will purchase the property on these conditions: First, to investigate the mine, and, if the price is suitable, they will take it upon conditions that they have ninety days to explore the same, keeping all the ore to defray the expenses of exploration. If they find the property to be worth dollar for dollar of $800,000, they will pay that; if not, they will make an offer for just what is in sight.

NORTH STAR.—The *Herald* says that the rumor that the North Star mine, on Sultan Mountain, had been sold for $450,000 is contradicted, and by reference to the recorder's office, we find a bond and trust deed has been given to Mr. Lucius B. Kendall, with a cash payment of $10,000 giving L. B. Kendall & Co. entire control of the mine. This will be somewhat of a surprise to those interested, as the North Star is considered worth at least one quarter of a million. We are informed that Mr. Kendall has purchased the mine for the purpose of proper development, and expects to expend $25,000 before any remuneration will be expected. Two big contracts will be let upon the North Star in the third and fourth levels, and the property otherwise developed in systematic shape for production. Mr. J. L. Lattin will be retained as manager and resident superintendent, and all work at the mine will be contract work.

SUMMIT COUNTY.

GOVERNOR.—The Governor Mining Company, on the Upper Blue, is putting up a building 40 by 75 feet, to put machinery in for concentration, which, when completed, will treat forty tons of crude ore per day. The machinery is ordered and will soon be on the ground. The mill ordered for the Governor is similar to that used by the Payrock Mining Company at Georgetown, which has proved a complete success in every particular on ore similar to that of the Governor group.

DAKOTA.

FATHER DE SMET.—The report of the superintendent, from July 14th to July 22d, shows ore extracted from the first, second, and third levels, 1900 tons. Ore milled 1900 tons. Golden Gate east cross-cut, third level, advanced 12 feet; commenced 5th July. The clean-up of the mine for the first half of July yielded $15,065.31.

IDAHO.

BANNER.—The Banner mill started up the other day with 15 stamps, and already several assays have been made. The assaying is better than ever before, running from 109 ounces to 113 ounces.

WOOD RIVER REGION.

MOUNTAIN BOY.—The Little Wood River Mining and Smelting Company has purchased the Mountain Boy mine for $10,000. The mine is situated at Muldoon, and is regarded as one which, if developed, will give large profits over all expenses.

NORTH STAR.—The ore-bodies are opening up so well that the superintendent has ordered concentrating-works, which will be delivered in two or three weeks. As he will have every thing else ready when the engine and jig arrive, it will not require over a week thereafter to start up the works.

STAR.—The Star group of mines, which is located in Star Gulch, about a mile and a half southwest of Hailey, has changed hands, the purchase price having been paid over last night. The figures are unknown, but variously stated at from $65,000 to $100,000. The sellers are David Falk and A. Wolters. Mr. Falk retains a fourth interest in the property. The purchasers are Moses Hirschman, Louis Martin, Emanuel Kahn (of Kahn Brothers), and J. W. Willard. All are Salt Lake parties. The Star was one of the earliest locations made in the Lower Wood River valley, and one of our first yielding mines. It has never been worked very steadily—probably not over eighteen months, all told—yet it has yielded to date some $85,000 worth of ore which averages probably as high as $175 per ton. The ore carries some sulphur and zinc, but that only means an additional cost of $7 to $10 per ton for smelting—an extra expense for which the high grade of the ore more than compensates.

MICHIGAN.

COPPER.

WILMOT.—The Wilmot Mining Company is the name of a new organization, on lands owned by Dr. Garlick and others, of Ohio, and O. N. Andrews, of this place, being the S. ½ of S. W. ¼ and S. W. ¼ of S. E. ¼ of Sec. 15, and N. ½ of N. ½ of Sec. 22, and N. W. ¼ of N. W. ¼ of Sec. 23, all in town 50, range 42. This is the tract where explorations were carried on last season, with a view of locating the Nonesuch vein in the slate belt. The land lies about five miles to the south and east of the Nonesuch mine, and two and a half miles southeast of the White Pine mine. Early this spring, Dr. Garlick sent up a steam oil-well drill under the superintendence of Mr. Stratton, which has been set up and found to work admirably. One hole has been put down 44 feet on to the conglomerate

Digitized by Google

belt, which lies under the slate belt in which lies the Nonesuch vein. The drill has been moved about 100 feet northwest, and will continue its work until the outcropping of the vein has been found, when a shaft will at once be sunk on it.

IRON.

The entire force, numbering 400 men, at the Republic mine, at Humboldt, went on strike on the 1st, for an advance of wages of 12½ cents. The president of the company told the men to confer with the executive committee at Cleveland. Much excitement but no disorder prevails.

MONTANA.

DEER LODGE COUNTY.

ALICE.—The *Miner* says that the Alice has for some time past been looked upon as the mine which would eventually solve the problem as to the depth of silver-bearing ledges in this camp, and especially on what is known as the Rainbow lode. The systematic methods of mining and extensive operations of this company have already developed the three veins of the Rainbow lode sufficiently to fully demonstrate their value and extent to a lower depth than has been reached in any other mine. The ledge, which has been stripped for a horizontal distance of nearly 400 feet on the 100 level, has also been developed on the 200 and tapped on the lower levels. The winze from the 700 has been sunk in ore the entire distance to the 800, at which point a cross-cut has been run to the north wall of the ledge and one is driving south. Thirty feet of vein-matter are now exposed in the cross-cut, and it is expected that the south wall will be reached in a distance of 30 feet farther. The ledge maintains the same general characteristics as in the upper levels, and further cross-cutting will undoubtedly develop the same sixty feet of vein-matter carrying the three veins of pay-ore so well known as the north, south, and center veins of the Rainbow lode. A west drift has been run 30 feet on the ledge from the bottom of the winze, and the drift has now two feet of good pay in the face, while the ledge maintains the general character developed above.

HOPE.—Prospecting with the diamond drill is successfully prosecuted in the Hope mine at Phillipsburg. In five weeks, 1100 feet have been drilled at an average cost of sixty cents per foot.

The Granite Mountain Company has ordered a diamond drill with which to prospect its valuable property. If the experiment proves satisfactory, several other drills will be used in the camp.

NEVADA.

Reports reach the Eureka *Sentinel*, through reliable sources from Osceola, that the Monroe & Linton mine, located at that place, has been sold to Charles Tozier, of San Francisco. The purchase price is not stated, but it is thought to be about $25,000. Machinery for a mill is on the road by way of Salt Lake. The mill will be located within a few hundred yards of the mine. If the mill proves a success, there is a bright future before Osceola.

A committee from the Carson mills visited all of the ranches along the river, where to find the most shameful waste of water. In some instances, the ranchers had turned the water on the sage-brush, and were letting it run to waste, simply to keep other ranchers from using it. In places, they found bodies of water ankle deep, covering hundreds of acres, and doing no good to any one. Some years ago, the United States Court gave the mills a perpetual injunction against the ranchers for the use of the water. Carson City is threatened with a water famine, and one man who illegally diverted the water has been sent to jail for 250 days and fined five hundred dollars. The law will be invoked against the ranchers to compel them to give the mills enough water to run their stamps.

COMSTOCK LODE.

The joint Union Consolidated and Sierra Nevada west cross-cut, on the 3000 level, says Tuesday's *Enterprise*, is still driving ahead. This cross-cut found the ore-vein cut on the 2900 level to be 30 feet in width on the 3000, whereas on the level above it had a width of but 11 feet. After passing through this thirty-foot vein, the cross-cut came to a streak of porphyry nine feet wide, and next found a vein of milling ore seven feet in width. West of this, porphyry again comes in, and the cross-cut had last evening been advanced into this about five feet. They will push ahead, as it is not unlikely that, after going a few feet farther in porphyry, they will again come to ore. It is some 500 feet to the west wall of the Comstock lode, and the ground into which they are now passing has a very kindly appearance. The seven-foot streak is something new. It did not show on the 2900 level. The 30-foot vein is undoubtedly the continuation of the 11-foot vein found on the level above. Even though nothing be found in going farther west, they may now start a drift south, the full width of which will be in milling ore. This new streak, and the formation into which they are now passing, look well for Sierra Nevada. There are indications that the ore will make north as well as south. There is also much of interest about the winze (down from the 2900 to the 3000 level) and in the east end of the cross-cut therefrom. This winze will, in a day or two, be continued toward the 3100 level, and it will start off in quartz. Before it is 50 feet in depth, it will cut into the fine streak of quartz (in all, some ten feet wide) which was claimed by many to be the vein cut above on the 2900 level. This is a different character of quartz from that of the eleven-foot vein above. It shows very little gold. Both this and the quartz streaks cut in the winze are essentially silver-bearing material, while the thirty-foot vein and the seven-foot vein run unusually high in gold. It is not unlikely that the porphyry separating all these streaks and veins will wedge out before the 3100 level is reached, thus forming a large ore-vein. However, supposing them to hold as at present, the cross-cut from the winze will have but a short distance to go on the 3100 level before it will reach the thirty-foot vein.

EUREKA DISTRICT.

ALBION.—Albion has been shipping ore daily for the last week to the Eureka Consolidated furnaces at the rate of 15 tons per day. Prospecting and ore extraction are carried on with a force of 20 tributers and men on day's pay. The mine shows considerable improvement generally. The tributers have good paying pitches, and the company's men are at work on good ore.

CHRISTIE.—The tailings at Mineral Hill owned by this company amount to 30,000 tons, an average of which taken for sample by R. D. Clarke, superintendent of the Geddes & Bertrand, who has lately inspected the property, assays from $15 to $20 to the ton. The question is, how to reduce these tailings at a profit. They can be made to pay by the ordinary mill process now in use on the premises; but a cheaper way is looked for, by which the maximum can be saved and a big clean-up made. Mr. Clarke makes a safe estimate that a leaching-plant can be put up on the grounds at a cost of $25,000 that will reduce 40 tons per day and save $6 above all expenses per ton. The profit on the 30,000 tons at this rate, less $25,000 for leaching-works, would leave a net balance of $155,000. In addition to this, there are 15,000 or 20,000 tons of $25 and $30 ore on the dump near by, that could be reduced at a profit of $5 per ton by the same process. This ore then, taking the lowest figures, should net $75,000, which, added to the profit from reducing the tailings, $155,000, would swell the total profit to $230,000.

EUREKA CONSOLIDATED.—The drift from the new shaft is in 140 feet without any change of formation, continuing in black lime. The drift is still dry, no water having been encountered. At 80 feet, the drift entered a body of clay which gave some trouble, requiring very heavy timbers. The ground in the face is firmer, and does not swell. The progress in drifting is about 40 feet per week. The Eureka Consolidated mine has not changed in any noteworthy manner since the last report. Another, the second, furnace was started up on Friday. The two furnaces together reduce about 100 tons per day.

NEW MEXICO.

The smelter of the Colorado & New Mexico Mining and Smelting Company, located at Magdalen, Socorro County, New Mexico, and owned by Messrs. Kerr, White, Fairley, Clark, and Sinclair, has been blown in. It is treating the ores taken from the mines of this company, and from eight to ten tons of bullion are shipped daily.

The Rankin Smelter, at Copper City, yesterday shipped 7000 pounds of copper bullion to Bernalillo. It is the first shipment, and it shows conclusively what there is in the district.

PENNSYLVANIA.

A vein of iron ore has been found in Plum township, on the eastern border of Alleghany County, which is said to assay 60 per cent. Native ores ordinarily assay from 25 to 40 per cent. Some of those who have seen it say it is the best foundry ore found in this section. The vein is located three miles from Logan's Ferry, on the Alleghany Valley road, on the farm of Alexander McJunkin. The man who discovered it was formerly a puddler. Mr. McJunkin has been busily at work digging out the ore for some time past, and will soon send down to Pittsburg three car-loads, which will be used by some of the iron mills there. The vein has a regular thickness of eight feet, and is said to be solid.

UTAH.

CAVE.—The main working tunnel, starting in the western face of the mountain, a good distance up, yet not so far but that a good wagon-road has been made to it, has been driven in 700 feet. Here, a hundred yards beyond the old workings, a stained kind of a wall was struck, which was followed southward two hundred feet or so, when it began to change into ore; and while this new country has not been thoroughly explored as yet, there are estimated to be perhaps 12,000 tons of $30 (net) ore in sight. The general average of the ore in car-load lots is 50 lead, 26 silver, and half an ounce of gold, with perhaps 25 per cent iron, the lead being all carbonate and fluxing itself, making the iron in the ore available for fluxing dry ores. It is no longer delivered at Frisco; it is proposed to induce the railroad to extend a switch out near the mine from Milford, and send it, as also the ores of the Carbonate mine, to Sandy.

EMMA.—Work on the old Emma mine, Alta, is progressing finely. The shaft has reached a depth of 200 feet and is still going down. A cross-cut on the 135-foot level has penetrated 165 feet, and will soon tap an incline sunk by the present company some three years ago, at which time work was suspended on account of water. This cross-cut is in good ground, and has tapped the ledge 250 feet below the workings of the old Emma. Thirty men are employed on the property, and it is probable ore-shipping will begin within a few months.

MAMMOTH.—The Salt Lake *Tribune* says that the Mammoth property, Tintic, is in a fair way to be placed in working order soon. It will be remembered there has been trouble, which a few months ago caused the smelters and mines to shut down, since which they have remained idle. This trouble came mostly through the failure of the English parties who had taken hold of the property, and failed to make payments to employés and creditors. Mr. Goodhart came here from London a short time ago, as attorney for the English capitalists who had invested in the property, and made the McIntyre Brothers a proposition, which has been accepted, and which, on the payment of certain moneys next month, will place the property in the hands of the English purchasers. If they comply with their part of the contract, it is probable that within the next thirty or forty days the mine and smelters will be again put in operation.

ONTARIO.—The big tunnel for the Ontario mine will soon be completed and in full running order. This tunnel starts from a point below the mill, under which it runs, ninety feet below the batteries, and ends at shaft No. 3, where the big Cornish pump is located. The distance is 5742 feet, nearly all the way through hard rock. Work was begun in June, 1881, but the progress was slow the first year, as the work was all done by hand. Since introducing air-drills, one year ago, the progress has been very rapid; in fact, the best speed at driving such tunnels that we know of has been made. An intermediate shaft 300 feet deep was used to expedite the work, and at one time there were four headings in progress at the same time. Since last March, the work has been pushed more rapidly than ever, and during the time 2900 feet were pierced. On the night of July 22d, connection was made between shaft No. 3 and the intermediate shaft, and nothing now remains to begin using the tunnel in draining the mine except to place a flume 2800 feet in the bottom, to complete the water channel. This will require about three weeks' time, and then the lift of water from the mine will be shortened 500 feet from what it is now. At present, the water is pumped from the eighth level to the union tunnel, 100 feet below the surface, while the new tunnel taps the shaft on the 600-foot level. The cost of hoisting water will be reduced to less than one third that of the old system, and this will gradually increase as the mine is sunk below the 800-foot level. A short time ago, there was an increase of water in the mine, and it rose some distance, but did not get up to the 600-foot level, as reported, by a long ways. Extracting ore goes steadily on from all the levels, and the property is looking as well as, if not better than, ever before.

STORMONT.—The superintendent's report, dated July 14th, shows that the mine and mill are running on full-time, and the shipment of the full quantity of ore required to mill. The strike on winze 15 is producing well, and also strike on winze 23; and during the week, about 75 tons of good ore were hoisted from the old Buckeye works. The total ore for the week sent to mill was 287 tons. On the 12th of July, work was begun on sinking the main incline to the sixth level. The vein on the incline is similar in appearance and quality of ore to that in the fifth level south. Assays, July 15th, showed as follows: 10 inches, $8.11 per ton; 12 inches, $116.84 per ton; 12 inches, $116.21 per ton. Gross bullion to July 1st, $114,307.95.

YOSEMITE.—This mine, at Bingham, is turning out its regular quota of ore, and is operated by a force of twenty men. In this mine, there is an immense body of ore, part of which is low-grade, requiring concentration. For this purpose, the company, some time ago, erected a concentrator, operated by a small steam-engine, and it does its work to the satisfaction of the owners. First-class ore is sent to the sampler without concentrating, and this amounts to about one half the product in tons, or 100 tons per month of first-class ore and 100 tons concentrated. The process of concentrating is simple and not very expensive. Second-class ore as it comes from the mine is emptied from the cars by dumping on to a slanting screen. The finer portions pass through the screen and fall on one portion of the floor, while the lumps pass beyond. On this floor is the rock-breaker, and beneath it a feeding-apron. The ore in lumps is thrown into the crusher and the finer on the apron, and all is fed to the Cornish rolls below, so as to pass evenly through them, dropping into a spout which conducts into a revolving screen. In this spout the ore is caught and carried by a stream of water, which aids in washing away the lighter and useless portions, while the ore drops through screens and reaches the jiggers. There are three of these revolving screens set on an angle, so as to give a good fall from the crusher to the end of the last screen. Each screen has its jiggers to complete the work of concentration. The mill treats thirty or forty tons of crude ore per day, reducing three and five to one. The mine is operated by an incline, and has good hoisting-works, pumps, etc. George W. Crow is superintendent of the mine and mill. All the water used in concentrating ores is pumped from the mine, and the quantity is not great enough to keep the mill running more than about twelve days per month, which is ample at present to do the work for the quantity taken out. All the ore is hauled by teams to the sampling-works at Sandy.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Aug. 3.

The mining market this week has been very dull, and the transactions have been mostly confined to a few stocks. Of these, Consolidated Virginia, Robinson, Eastern Oregon, Sonora, and Alta-Montana take the lead. Prices have generally been steady, but there is no marked change either way to note. Below is given a full summary of the market The total number of sales aggregates 190,513 shares, as againnst 235,354 last week.

The Comstock shares have had a fair business at steady prices. California was active and strong, selling from 26@38c. Consolidated Virginia had a very active business and was also strong; it sold from 28@36c., assessment unpaid. Sierra Nevada was quiet and steady at $4@$4 15. Union Consolidated sold at $4.85. Mexican was dealt in to the extent of 300 shares at $3@$3.10. Hale & Norcross sold at $6. Sutro Tunnel was moderately dealt in at steady prices, selling from 19@20c.

The Leadville stocks were very quiet, and were steady. Amie sold from 15@14c., with a small business. Chrysolite was quiet and steady, selling from $1 15@$1.20. Dunkin sold at 22c. Iron Silver, with a business of 700 shares, sold at $3.05. Leadville sold at 51c.

The Bodie stocks were also very quiet at steady prices. Bodie sold at 70c., and Bulwer at 76c. Standard records a small business, and was strong, selling from $6.25@$6.13@$6.50.

The Tuscarora stocks were moderately dealt in, and were steady. Belle Isle sold at 43@40c., with a small business. Navajo was strong, selling from $3.10@$3.25. North Belle Isle sold at 35c. Independence was quiet and weak, declining from 50@43c. Elko Consolidated was moderately dealt in at irregular prices, selling from 19@14@15c.

In the miscellaneous list, Alice has been quiet and weak, selling from $2.50@$2.25. Bassick was a little weak at $10@$9.75. Eureka Consolidated has been strong under a small business, selling from $4.50@$5.50. Green Mountain was quiet and steady, selling from 75@77c. Horn-Silver records a moderate business, and was irregular, selling from $7.25@$8@$7.63. Hukill, with a small business, was quite weak, declining from 6@4c. Northern Belle sold from $7@$6.75, with small transactions. Robinson Consolidated was very actively dealt in at very irregular prices; it sold from 72@90c., then declined to 62c., closing to-day at 68c. Sierra Grande has had a small business at irregular prices, selling from 96c.@$1@95c. Stormont records a fair business, and has been steady, selling from 37@35c.

Alta-Montana, with a very active business, has been irregular, selling from 8@5.@6c. Central Arizona was quiet and steady at 15c. Decatur sold at 4c. throughout the week; the transactions were small. Eastern Oregon was very actively dealt in at strong prices; it sold from 81@85c. Sonora Consolidated was active and irregular, selling from 28@24@26c. South Hite had a small business at weak prices, selling from 1@6@2c.

MEETINGS.

United States Bullion Refining Company, No. 56 Broadway, New York City. Special annual meeting for the election of trustees, August 8th, at twelve o'clock noon.

DIVIDENDS.

The Horn-Silver Mining Company, of Utah, has declared a quarterly dividend (No. 10) of $300,000, payable August 15th.

The Standard Consolidated Mining Company, of California, has declared its monthly dividend of twenty-five cents per share, payable August 13th.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson, petroleum brokers, No. 49 Broadway, report as follows on the petroleum market:

The principal factor in the market this week was the appearance of the monthly statement of development-work in the oil regions, which was far more bearish than expected. It showed 32 more wells drilling than thirty days ago, and 87 more rigs up and building than a month ago. Thus there are practically 119 more wells under way than on the 30th of June. Coupled with this was another bearish fact, namely, the increase in surplus of oil held in the custody of the Pipe Line companies of 404,461 barrels. Furthermore, Porcupine well No. 8 came in during the week, producing 800 barrels the first twenty-four hours, and now yielding at the rate of about 500 barrels daily. Several other wells came in as pretty fair producers, and there appears to be no scarcity of the crude product. Added to all this was the reduction of the price of refined oil ⅛c. per gallon. All these bearish influences served rather to prevent an advance than to cause a decline. The highest price, $1.09¾ was succeeded by $1.05¼ for the lowest, and at this writing prices are back to $1.08⅛. Opinion as to the future course of prices is about equally divided, and no radical change is likely to occur for some days, although the market is active.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
July 28	$1.08¾	$1.09¾	$1.06⅝	$1.06⅞	2,885,000
30	1.07	1.09	1.05⅞	1.08	3,432,000
31	1.07¾	1.09½	1.06⅜	1.06⅝	3,933,000
Aug. 1	1.06⅜	1.07½	1.05¼	1.06⅞	2,443,000
2	1.06⅞	1.07½	1.06¼	1.07	3,244,000
3	1.07⅝	1.08⅛	1.07¼	1.08⅛	2,492,000
Total sales					18,429,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, Aug. 2.

Since our last report, the market for copper stocks, although ruling extremely dull and inactive, has shown a somewhat firmer tone, and prices, as a rule, are a shade higher. There is no change in the market for ingot copper, which is selling about 15⅛@15¼c. for Lake, and other grades proportionally lower; but the feeling seems to be quite prevalent that the bottom has been reached, and some parties are quietly picking up all the stray lots of the dividend-paying stocks that are offered, in the expectation that higher prices will prevail before the year closes. There is no speculative element in the market, and in consequence all the non-producing mines are inactive, with only a sale now and then of a hundred or two shares, as a reminder that they are still in existence. Calumet & Hecla continues to advance, and sales at $245@$246 are recorded. The stock is not abundant in the market, and only small lots come out even at the advance; in fact, only two shares have been sold the past week at $246, although $247 has been bid for it, and it is doubtful if much could be bought even at $250. Franklin has shown some considerable activity and firmness at about $10, with a 50-share lot sold at $10¼, buyer 60. The holders of this stock are not disposed to part with it at this price, to any extent, and have not lost all hope of a dividend some time during the ensuing fall. Quincy is now selling, ex dividend ($3 per share), at $45½, which is about $½ higher than the last sale, dividend on. There is not much stock offering, and holders are well satisfied with the present outlook at the mine. A sale of five shares of Atlantic at $12 is the only transaction for the past two weeks. Osceola is steady at $21, but not much doing in it. The sale of the delinquent stock of the Pewabic and Huron mining companies on which the assessments have not been paid was held last week. Of the Pewabic, about 1000 shares were sold, the price ranging from $2½@$3¼ per share. Of Huron, less than 2000 shares were disposed of at an average price of about $1½ per share.

In the general market, Pewabic sold at $3¼, and Huron at $1½. Brunswick Antimony put in an appearance the past week with sales of small lots at $15@$16. The Douglass mine, of Maine, has levied an assessment of 25 cents per share, and the stock is offered in the market at 65 cents, assessment paid. This mine continues to look promising. The ore improves in the lower levels, and the production is about 1½ tons of ingot copper per day, and it is said that the company is fully paying its expenses. Should this mine prove a success, it will give a great impetus to mining interests in Maine.

In silver stocks, there is but little doing. Silver Islet, which had its "spurt" up to $7½, has declined to $5, and is now offered at that, $4 being best bid. Sullivan declined to 62½c., and is now offered at same price, 50c. bid. Catalpa advanced to 52½c., but declined to 47½c., which is now bid. Harshaw sells at 50c., and parties stand ready to take all offered at that price, although there is said to be about 70 cents in the treasury to divide among the stockholders. Only 250 shares of Bonanza have been sold the past two weeks, at $1⅞@$2.

At the Mining Exchange, there is but little of interest. Sales of Bowman Silver at 16@20c., closing at latter price bid. Massachusetts & New Mexico has faded from the public view, selling under 5c. per share, and, according to a rule of the Exchange, is no longer quoted. Empire is dull at 15c. bid, 20c. asked. Considerable business is developing in railroad shares, Toledo, Cincinnati & St. Louis being most prominent.

3 P.M.—The market closes dull and lifeless. For Calumet & Hecla $247 is bid. Quincy sold at $45½, and same bid. Franklin, $10 bid. Pewabic, $3. Osceola, $21.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Aug 3.

Mr. Edward J. Shriver, Secretary of the Metal Exchange, has collected the following statistics for 41 furnaces, relating to stocks and production in July:

Grade.	Stocks. July 1.	Stocks. Aug. 1.	Production in July.
No. 1	1,714 tons.	1,833 tons.	5,635 tons.
No. 2	4,505 "	4,968 "	2,582 "
Forge	5,868 "	5,807 "	8,612 "
Not specified	2,147 "	2,550 "	1,777 "
Total	14,234	15,158	18,606

These figures do not indicate that there has been any particular cause for improvement.

American Pig.—The market has been very quiet during the past week, and though there has been no change in prices and some grades are very firmly held, we find that it has lost rather than gained in strength. The supply of No. 2 is ample. We continue to quote $22@$23.50 for standard to choice No. 1, ordinary brands being obtainable at a concession of 50 cents; $19.50 $20.50 for ordinary to choice No. 2; and $18@$20 for inferior to choice Gray Forge. Bessemer Pig is dull at $20.50@$21 at tidewater, London cabling unchanged, 50@51s. for Nos. 1 to 3. Spiegeleisen is dull at $31@$32 for 20 per cent. The arrivals of English metal of high grade in quantity are pressing upon the market. Our American furnaces are now succeeding in maintaining a high grade over long periods regularly, but, of course, are unable to supply more than a small part of the demand.

At the Metal Exchange, the following transactions in pig-iron have been recorded thus far this week: Tuesday, 100 tons, No. 1, October delivery, at $21¾. Wednesday, 400 tons, No. 1, November, at $21⅝, and 300 tons, November, at $22. Thursday, 200 tons No. 1, October, at $21¾, 300 tons No. 1, October, at $22, and 100 tons, October, at $21⅞; and to-day 300 tons, November, at $21¾, 100 tons, November, at $21⅞, 100 tons, November, at $22, 300 tons, October, at $21⅝, and 100 tons, October, at $21¾.

Scotch Pig.—There has been an advance in

G. Gold. S. Silver. L. Lead. C. Copper. * Non-assessable. † Stocks quoted on S. F. San Francisco; B., Boston; P., Philadelphia. Non-Dividend shares sold, 82,050. Total shares sold, 190,513.

to carry themselves over the summer season. Neither quotations nor actual selling prices have changed Concessions are of rare occurrence. No new factors have appeared. A good deal of difference of opinion is expressed as to the shape trade will take during the latter part of this month and next. The leading companies are indifferent as to the course of demand, and are satisfied that the actual requirements will protect their interests against the low prices that some buyers talk about. The best makes of special Foundry iron still command $23.50, and prices range from that all the way down to $21.50, as usual. The most of this week's business was done between $22 and $22.50, and it seems probable that these figures will be maintained, as makers are putting forth no efforts to attract buyers. It is announced that some few furnace companies will resume in September; but this is uncertain as yet, as fall demand can not be accurately predicted. No. 2 iron commands $19.50@$21. Quite a number of small sales are recorded at $20@$20.50. The output during the past few weeks has not been up to the average. In Gray Forge iron, some few inquiries for 1000-ton lots have been made, and purchases have been partly arranged for. The surplus of anthracite iron is sufficient to protect buyers' interests. At present prices, there is very little room for further decline, and no temptation to increase the

Digitized by Google

supply. The mill-men hold back, and makers and brokers are not trying to push stocks on the market. The average business is done quietly, and both sides are waiting for something new. More or less inquiry is made for Bessemer iron, but transactions are unimportant. Buyers name $20. During the past week, some fresh inquiry has been developed for spiegeleisen. Sales foot up between 5000 and 6000 tons at $30.25 for 20 per cent.

Manufactured Iron.—Western competition is beginning to be felt in offerings at 2·10c., and hence buyers predict a drop in Eastern prices. The market is easy, and the consumptive requirements seem to be presented in a regular and even way, and are easily met by manufacturers. Selling prices average 2·20c., but large lots can not be moved at this price. Fall buying is expected to be done at 2·15c. Retail lots move easily at 2·25c.

Skelp Iron.—Sales are heard of, on private terms. A good deal of common iron has been bought at country mills. The lowest transactions known of are 1·90c.; highest, 2·10c.

Plate Iron.—This week's business has been similar to others. Sales run from 50 to 500-ton lots. A fair amount of business has been done. Where large orders are concerned, present quoted prices have been shaded. Prospective requirements are heavy.

Structural Shapes.—A fair business has been done, and prices are quoted firm.

Sheet-Iron.—Transactions are increasing in volume for fall requirements, and prices for large lots are perceptibly firmer, especially where prompt delivery is insisted upon. Galvanized iron is 40 per cent off; demand fair.

Steel Rails.—Small lots are chiefly called for, at $38.50. Winter deliveries are held at $38; buyers offer $37, at which figure negotiations are now in hand.

Old Rails.—No sales have been effected. Quotations are nominal.

Scrap is dull at $23@$25.

Pittsburg. Aug. 2.

The sensation here this week is the failure of L. B. Ward & Co., of Niles, O. It was brought about by the Graff, Bennett & Co., the Stone, and the Brown, Bunnell & Co. failures. The assets are trifling, and the liabilities are half a million dollars.

The iron market is healthier than it has been for months. The chief underlying causes are the facts that prices have reached the lowest possible limit; that production has been restricted; that stocks are low in consumers' hands; and that the future requirements of consumers are now presented. Prices are firmer but not higher. Offers made a month ago are now withdrawn. Inquiries are in hand for lots of iron from 100 to 1000 tons. The blowing out of so many furnaces is working good results. Quotations range from $16.50 for Mottled; $17@$17.50 for Gray Forge; $19@$20 for Foundry; Extra Forge, $18; Extra Foundry, $21; Bessemer Pig, $21, cash; Muck Bars, nominally $34. No sales.

BULLION MARKET.

NEW YORK, Friday Evening, August 3.

The market is firmer abroad to-day on a higher rate for exchange on India, but not quotably higher. An advance in sterling exchange here has slightly improved the rate here.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended August 3d, as compiled from various sources, amounted to $194,000, as against $228,500 reported for the previous week. The receipts from January 1st, 1883, to date are $6,717,974.

Foreign Bank Statements.—The governors of the Bank of England, at their regular weekly meeting, made no change in the bank's minimum rate for discounts, and it remains at 4 per cent. During the week, the bank gained £350,000 bullion; but the proportion of its reserve to its liabilities was raised only ⅛ per cent—from 44¼ to 44⅜ per cent, against 36¾ per cent a year ago. August 2d, the bank gained an additional £112,000 bullion on balance. The weekly statement of the Bank of France shows losses of 4,025,000 francs in gold and 1,300,000 francs in silver.

METALS.

NEW YORK, Friday Evening, August 3.

Copper.—The market is quiet. There is little demand for Lake, and very little of this class of copper is offering, the range being about 15@15⅛c. Other brands of copper show more strength, and there is a disposition on the part of those who handle them to hold out for higher prices. We touch on some of the features affecting the future editorially. London cables lower, £68 10s. for Chili Bars and £69 17s. for Best Selected.

Tin.—This metal has been moderately active, the spot stock, which probably does not aggregate more than 1000 tons, being firmly held by strong parties, so that it is a difficult matter to get round lots of spot Straits or Malacca, which we quote 21⅛@21⅝c. Australian is easier. By cable, the shipments for the period of July 15th to 31st, from Singapore are advised as 230 tons to the United States, and 200 tons to Great Britain. London cables to-day £94 10s.

Lead.—The situation in this metal has not changed materially. Sales are on a jobbing scale exclusively, and while Common is freely offered at 4·30c., bids do not go higher than 4·25c., at which holders decline to sell as yet.

Messrs. John Wahl, of St. Louis, wire us as follows, to-day:

Our market is dull. Soft lead is freely offered at 4·05c. Sales for the week sum up over 300 tons of Refined at 4·03c. The best bid obtainable now is 4c. Hard Lead is quoted nominally at the same figure.

Messrs. Everett & Post, of Chicago, send us the following dispatch:

The market continues very dull, with no buyers. Business consequently has been very quiet and of a limited character. Prices are nominally 4·10c. for both Common and Refined.

Spelter.—This metal continues dull, with values ranging nominally between 4⅝@4⅝c. for good Western.

Antimony.—This metal is quiet, with quotations at 9¼@9⅝c. for Hallett's and 10¼@10⅝c. for Cookson's.

COAL TRADE REVIEW.

NEW YORK, Friday, Aug. 3.

Coal summarizes the situation as follows:

The trade continues with but few signs of encouragement. Current business is small in volume and is forced, notably on steam sizes, while middle-men are still engaged in placing the heavy amounts ordered by them in June, a work which is rendered more difficult because they have not the plausible argument of a nominal advance by the companies to fall back upon. One of them which is noted for taking good care of its contractors, will, as rumor has it, announce an advance in two weeks. So far as the others are concerned, they seem to have discussed the matter, arriving at the wise conclusion to let prices alone. Notice of a general advance of 10 cents a ton in the tolls on coal shipped both by rail and canal was given by the Philadelphia & Reading Railroad Company, to take effect August 1st. The new circular announcing the line and city and harbor prices of coal has been issued by the Philadelphia & Reading Coal and Iron Company. There is no change in the line and city prices, but the harbor prices embody the 10 cents advance in tolls, and are as follows: $4.30 for lump, steamboat, broken, and egg; $4.40 for chestnut; $4.55 for stove; and $2.55 for pea. These rates are for white-ash coal, and they are 25 cents higher on stove and chestnut, and 15 cents lower on pea than they were one year ago. Lump, steamboat, broken, and egg are unchanged from the prices of last August.

There is a good deal of speculation as to the probable quantity of coal which the market will be expected to take this year. On the 1st of July, the increase of this year over last was roughly 1,450,000 tons, in spite of the fact that there have been 51 idle days. This is usually interpreted as showing how much more active consumption has been, while it should really be read as showing how much the productive capacity has increased, probably partially under pressure. A large share of this increase has gone to Western distributing points, which are now full to overflowing, so that Buffalo is now beginning to stock to some extent. As yet, the work of distribution of this great quantity of coal has not fairly commenced, and the trade will look with anxious interest to the time when the good work is fairly started. The movement Westward must, however, soon abate to some extent, and the tidewater markets will receive greater quantities, which must be kept moving. With full-time and with a moderate line trade only, *it is* feared that there will be some accumulation here, and this is what consumers are looking and holding off for. A heavy domestic consumption later on may easily dispose of this coal, but until the middle or end of August not much business of this character can be looked forward to. The manufacturing industries are dull, and bituminous coal is very cheap, so that the trade for steam sizes is very quiet.

Such is the situation as it is now. Should the future prove a disappointment, which we sincerely trust that it will not, only one of two things is possible, either prices can not be maintained or production will have to be curtailed again. It is, therefore, a little too early to figure out the output, because it is possible that there may be more coal than is wanted. It will all be needed if domestic consumption is heavy; but this is a factor which is always uncertain to some extent.

At the meeting of the Western Association at Saratoga last week, prices were let alone. The chief topic of discussion was the adjustment of railroad freights to a number of inland competitive points upon which uniformity was aimed at. These points involve a great deal of detail, and are difficult to settle satisfactorily to all parties concerned.

Bituminous.

The trade is as dull as ever, with no new features worthy of note.

Horsford's Acid Phosphate

In Liver and Kidney Troubles.

Dr. O. G. CILLEY, Boston, says: "I have used it with the most remarkable success in dyspepsia and derangement of the liver and kidneys."

THE BERKSHIRE HILLS.—A new Colored Map, 22×28in., showing mountains, lakes, rivers, valleys, hamlets, railroads, highways, and points of interest, free to any address. Apply to BERKSHIRE LIFE INSURANCE CO., Pittsfield, Mass.; or its General Agent, 271 Broadway, New York City.

TO COAL COMPANIES AND DEALERS.—A gentleman of energy, experience, and extensive acquaintance desires position for selling to steamship, railway, and manufacturing companies. Address B. B. W., 1238 Broadway.

DIVIDENDS.

HORN-SILVER MINING COMPANY, Office, 44 Wall Street,

NEW YORK, July 31, 1883.

DIVIDEND NO. 10.

QUARTERLY DIVIDEND of $300,000 has been this day declared, being three per cent on the capital stock, payable to stockholders of record on the 15th day of August next, at the office of the company. Transfer-books will close on August 8th, and reopen August 16th.

W. S. HOYT, Secretary.

THE Amalgamated Association of Iron and Steel-Workers is indulging in its annual convention in Philadelphia, and is making a great show of secrecy. It is stated that financially the Association is falling behind, and that an assessment to cover a heavy drain from the treasury is soon to be called. The association reports a membership of 49,000.

ONE of the most gratifying signs of progress in the utilization of steel is its adoption as the raw material in the manufacture of nails. Among makers it appears to be now the great topic of discussion and the principal object of experimental work. Thus far, the latter has afforded much encouragement, and we hear from a number of sources that the building of steel plants to produce a suitable raw material is contemplated.

WE regret to announce the sudden death, from paralysis, on the 10th ultimo, of Mr. RAIMUNDO DE SANTA MARIA, at the residence of M. ADELON (the legal adviser of Prince NAPOLEON), at Arpajon, near Versailles. Mr. DE SANTA MARIA was a graduate of the Ecole Spéciale des Hautes Etudes, was admitted as a public assayer of the French Mint, and likewise as consulting chemist of several metal-working establishments at St. Denis. He was, during a brief residence in the United States, connected with the Canada Consolidated Gold Mining Company as assayer. His social qualities had attracted many friends to whom his untimely death in the twenty-fourth year of his age will prove a great shock.

FROM Colorado comes the news that the Grant Smelting-Works and the Omaha Smelting and Refining Company were consolidated some time since. For years, the relations of these two concerns have been close, like a number of other works engaged on the one hand, in the smelting of ores, and on the other, in the refining and desilverizing of the base bullion so produced. In their efforts to obtain regular supplies of base bullion, refiners have repeatedly endeavored to do their own smelting in subsidiary works ; but the present consolidation is, we believe, the first on record where two great, independent works have united their interests. For many reasons, the advantages of such a course are great, and we should not be surprised to see the example set by the Grant and Omaha works followed by others.

A SUGGESTION comes from England, which, we believe, spelter manufacturers would do well to consider seriously. All over the world, spelter is cast in thin slabs, probably because it has always been done so since spelter was made. Mr. J. B. SHARP, of Birmingham, urges that in that form it is about as bad as it could be for causing loss by volatilization, when melting in the preparation of copper-zinc alloys, and for retaining lead impurities, which adhere to the lower part of the film in thin flakes which are not removable. He insists that the best way would be to cast the spelter in the form of round 3 or 4-inch ingots, vertically, keeping the mold hot when casting and allowing it to cool slowly. The form would be more convenient and more advantageous for remelting, and the lead would gather at the bottom in a piece which could easily be detached.

MUST THE FARMERS GO?

In the trial of the suit of the People of the State of California *against* the Gold Run Ditch and Mining Company, some interesting evidence was given concerning the injury done by agriculture to the "navigable waters" and alluvial bottom-lands of that State. In California, as everywhere else, the cutting down of the forests on the mountain-sides, while it has not, in our opinion, changed the annual rain-fall perceptibly, has increased the tendency to freshets and floods, by accelerating the collection and flow of meteoric waters. Together with this change, another agency has made itself felt. The annual plowing of the valley soils, loosening the sand, loam, and clay of which they are composed, has given rise to vast quantities of easily-moved *débris*, which are carried down into the rivers and bays. The aggregate injury thus inflicted is undoubtedly greater than any which can fairly be ascribed to the *débris* from hydraulic and placer mining, although in single localities the latter industries may be responsible for direct damage.

A strong argument, which might have been made still stronger by more abundant details, was based upon these facts, in the case alluded to. The shoaling of such streams as the Sacramento having been ascribed to the hydraulic mines, although in fact due in great degree to agricultural *débris*, a comparison was instituted with other streams, at the headwaters of which no mining is carried on. A good example is furnished by Pacheco Creek, in Contra Costa County, the drainage area of which comprises 177·3 square miles of valley and hill land, and 6·5 square miles of marsh. The valley is bounded on the east by the Monte Diablo range (less than 4000 feet high) and on the west by low hills. There is little disintegration from frost.

The soil of this valley is black "adobe," hard in summer and soft when wet. Before 1862, there being little or no plowing in the valley, no change was noticed in the surface of the valley ; but since that time, the hill-slopes have been cut up with innumerable ravines, and the *débris* from this natural hydraulic operation have been carried down to near the mouth of the creek, have covered up 2500 acres to the average depth of two feet, and have formed a large bar in Suisun Bay. Pacheco, once the largest town in the county, has been covered to the depth of eleven or twelve feet, and is nearly abandoned by its inhabitants. Vessels are already unable to come up beyond a point one and a half miles below the old "embarcadero ;" and the entire abandonment of navigation on the creek can only be prevented by vigorous appropriations in the River and Harbor bill.

The above facts indicate that agriculture has led to the average degradation of the surface of this drainage area at the rate of at least one foot in 443 years (assuming the deposit of two feet over four square miles in twenty years, and leaving out altogether the bar in Suisun Bay).

Similar calculations show that Alameda Creek is degrading its drain-

Digitized by Google

age area at the rate of one foot in 783 years, and Quercus Creek, draining only twelve square miles on the west slope of Mount Diablo, has brought down 2,600,000 cubic yards of *débris* in four years, or at the rate of one foot average depth in eighteen years.

The following estimates are given for the purpose of comparison:

Authority.	Stream.	Drainage area in square miles.	Years required to erode 1 foot from this area.
Humphreys and Abbot	Mississippi.	1,244,000	4,640
Everest	Ganges.	400,000	1,751
Lombardini	Po.	26,490	729

Professor DAVIDSON, of the U. S. Coast Survey, has estimated the drainage area of the Sacramento at 25,000 miles, and its erosion, from all causes other than mining, at 19,000,000 cubic yards, washed annually into the lower river. The State Engineer, on the other hand, estimates the total amount of material carried by the Sacramento in suspension (apart from sand rolled along the bottom) at 18,000,000 yards, and charges mining with 13,200,000 of this. According to Professor DAVIDSON, the Sacramento *natural* erosion would degrade its area one foot in about 1550 years; according to the State Engineer, the rate is only one fourth as great; or, in other words, the Sacramento Valley suffers much less natural erosion than that of the Mississippi, the Ganges, or the Po, although smaller valleys in the State show much more. The State Engineer's conclusion is not probable; Professor DAVIDSON'S is probable; and we wait with interest for somebody to raise the cry that the farmers must go! But these long conflicts are a great waste of time. Why not make every body go, and done with it?

NEW PUBLICATIONS.

THE MATERIALS OF ENGINEERING. Part II. IRON AND STEEL. By ROBERT H. THURSTON, A.M., C.E. New York: John Wiley & Sons. 1883. 8vo, 680 pages. (*Index.*)

We have looked forward with particular interest to Professor Thurston's second volume on *The Materials of Engineering*, because it is in iron and steel that he has done much original work, and because, during the past ten years, such an enormous mass of material has been accumulated by investigators and engineers, both here and in Europe, which Professor Thurston's skill could be trusted to present in a well-digested form. He has gone much farther in one respect than we had expected, and probably, knowing how many who seek in vain for information, in convenient form, on the methods of manufacture of iron and steel, he has reserved more than one third of his work for a treatise on that subject. Forming, as it does, a somewhat elaborate introduction to the main subject, the mechanical qualities of iron and steel, it comes up for discussion first. On the whole, it is well written, and will be sure to give the mechanical engineer a fair idea of the methods and aims of the iron-master and the steel-maker. After a number of chapters, general and historical in character, Professor Thurston takes up iron ores, giving fairly well their characteristics, notes on their occurrence, and numerous analyses from leading localities. He is occasionally led into slight errors, among which we may instance that, on page 71, he declares that zinc found with spathic iron ore is of value in the process of reduction. In speaking of the character of ores, page 95, Professor Thurston says: "When possible, magnetic ores are selected, where the cast-iron produced is to be made into fine cast-steel. Specular or magnetic ores are suitable for 'low' steels and fine wrought-iron, and the other ores make foundry iron of various qualities." We fear that the majority of iron-masters do not live up to these rules, even if they have the choice. Turning to blast-furnace practice, a number of rather ancient-looking furnaces and hot-blast stoves are illustrated, the chapter otherwise being a careful compilation from the very voluminous literature on the subject. The chapter on wrought or malleable iron is similarly elaborate, and particular attention is paid, as should be the case, to rolling, because it is at this stage that the interest of the constructing engineer in the methods of manufacture begins, and here too, Professor Thurston is evidently more at home. Over fifty pages are devoted to the manufacture of steel, and constitute the best summary of that industry which we have yet seen.

This concludes the first part of the work, the chapter following treating of the properties of iron and steel, a chapter into which Professor Thurston has crowded much of the material so industriously accumulated by engineers and metallurgists, during the past ten years, on the relations between the mechanical properties and the chemical composition of metals. This chapter, too, is worthy of close study by both mechanical and metallurgical engineers. Chapter IX., on the strength, elasticity, and resilience of iron and steel is of course the *pièce de résistance* of the work, covering, as it does, over one hundred pages. It discusses elaborately the methods of testing, and gives the results of standard work in this direction, while the following chapter discusses the conditions affecting strength, the effect of temperature and time, age and exposure, crystallization, the flow of metals, shock, overstrain, and repeated variations of load as modifying the resistance of iron and steel. A useful chapter on specifications, tests, and inspection brings the work to a close. We do not hesitate to urge all those who are interested in the subjects discussed—and what iron and steel master and mechanical engineer is not?—to closely study the book, which presents so much valuable material in a clear form, much of it being directly available to those only who have access to large libraries. A very large proportion of the data is the result of personal researches and inquiry.

THE air-receiver at Grace furnace, owned by the Brier Hill Iron and Coal Company, of Youngstown, Ohio, exploded recently, dangerously wounding the engineer and injuring two others. The engine-house was blown to pieces.

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. We do not hold ourselves responsible for the opinions of our correspondents.]

The Statistical Position of Copper.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Referring to the letter from your correspondent "Specular," in your issue of June 2d, in which he figured a surplus of 75,000,000 pounds of copper to be on hand at the end of the current year, and to your editorial in your issue of August 4th on the Copper Market, I beg leave to submit the following detailed figures, which I believe to be nearly correct:

	Pounds.	
1. "Specular" assumed a surplus of 42,000,000 pounds on hand January 1st, 1883. I believe this to be too large; but for the sake of comparison I start on the same basis,		42,000,000
2. You state in your editorial that the lake production is increasing; but the figures for the June production show a falling off of 750,000 pounds of fine copper, as compared with the average of last year—assuming the production to be the same—and present prices are certainly no encouragement for increased production. The production will be 55,000,000		55,000,000
3. The Western mines at present producing, known to the writer are:		
Arizona—The Copper Queen	7,500,000	
Detroit	3,000,000	
Old Dominion and Long Island	3,500,000	
Longfellow	2,500,000	
All others	2,500,000	19,000,000
Montana—Montana Copper Company	8,000,000	
Parrott Copper Company	6,000,000	
Belle Copper Company	2,500,000	
Anaconda and Allied mines	6,000,000	22,500,000
Other production and importation		7,000,000
Grand total		145,500,000
The export sales already made are:		
Lake Copper		10,000,000
Arizona bars		2,000,000
Montana mattes		12,000,000
Other ores, bars, and mattes		3,000,000
Ingot copper not lake		3,000,000
Total		30,000,000

Deducting this amount exported from the total production, we have left 115,500,000 pounds, and taking from this "Specular's" estimated consumption of 72,000,000 pounds, we have left a balance of 43,500,000 pounds.

Necessary stocks on January 1st:	
Lake copper to fill sales from January 1st to June 1st	20,000,000
Stock accumulated at mines	8,000,000
Stocks in hands of dealers, consumers, and in transit; say one month's consumption	6,000,000
Stock in refiners' hands and in transit to refineries	5,000,000
Total	39,000,000

Which, deducted from the above balance, leaves a surplus above bare necessity of 4,500,000 pounds.

If present prices continue, there must still be exported:	
Montana mattes	4,000,000
Ingot copper not lake	1,000,000
Arizona bars (all bars not held here by contract with refiners, as at least one cent per pound of copper more can be realized by shipping than by refining here)	4,000,000
Other ores, mattes, and bars	1,000,000
Total	10,000,000

or a deficiency of 5,500,000 pounds.

In other words, instead of showing a pressing surplus, the indications are, that the market will be short of copper this winter unless a change in prices stops the outward flow of copper. "REFINER."

[The letter of our correspondent confirms, in a general way, the conviction that has been gaining ground, and to which we have repeatedly given expression recently, that here the statistical position is favorable, even taking the lake product at 58,000,000 pounds, which we believe it will certainly reach, especially when the new plant of the Calumet & Hecla is running to full capacity. We presume that the product of the Boston & Colorado works, at Butte City, Montana, is included by our correspondent in the lump figure, 7,000,000, which represents the product of California, Nevada, New Mexico, Colorado, Wyoming, Missouri, the Eastern and Southern States, and copper in imported ores and pyrites. We are inclined to doubt, notwithstanding the fact that Vermont has stopped work and Utah has shipped very little, whether this figure will cover the entire output, but it does not affect the main issue that the metal is now in good shape. The only danger to it is a falling off of values abroad.—ED. E. AND M. J.]

NO MELTING CHARGE ON TRADE-DOLLARS.—At the suggestion of Superintendent Snowden, of the Philadelphia Mint, the acting director of the mint has issued an order to remove the melting charge imposed on trade-dollars deposited at the mint on account of sales of silver bullion. This action was prompted by the thought that, as all holders of trade-dollars who bought them at par and who offered them for conversion into bullion, suffered a loss of 18 per cent, it would be an additional hardship to compel them to pay the melting charge, which amounts to $1 for every "melt," or one per cent.

THE DIVINING-ROD.*

By Rossiter W. Raymond, Ph.D., New York City.

(*Continued from page* 65.)

The Jesuit father, Cæsius (*Mineralogia*, 1636), inclines to deny the efficacy of the rod.

Robert Fludd (*Philosophia Moysaica*, 1638), after mentioning the sympathy existing between the crab or oyster and the moon, between the rue and the fig-tree, between myrtle and the pomegranate, adduces as an instance of similar sympathy between plants and minerals the dipping of a hazel-rod over a vein of silver or gold.

The celebrated chemist, Rudolph Glauber (*Pars Secunda Operis Mineralis*, 1652) affirms from experience, and attributes to a physical property, the efficacy of the rod in exploring for metals.

The Jesuit father, Jean François (*Science des Eaux*, 1653), seems to admit the power of the rod to discover springs, but condemns its use.

The erudite Jesuit father, Kircher (*De Arte Magnetica*, 1654, *De Mundo Subterraneo*, 1678), having proved by experiment that rods of wood alleged to be sympathetic with certain metals, were, when balanced upon pivots, not at all affected by the proximity of these metals, concluded that the sympathy was chimerical. In his later work, he declared roundly that, if the movement of the rod did not proceed from a joke or a cheat on the part of the operator, it was not natural, and ridiculed those who fancied it could be caused by a vapor disengaged from the metal.

Edo Neuhusius (*Sacrorum Fatidicus*, 1658), believes in the working of the rod, and attributes it to a sympathy, or to the stars, or some other cause.

The Jesuit father, Gaspard Schott (*Physica Curiosa*, 1662), pronounces the use of the rod superstitious, or rather diabolical. But he adds, in a foot-note, that pious and honest men have assured him both with regard to the turning of the rod and with regard to the striking of the hours by a ring suspended within a glass (*pulsum annuli filo intra scyphum suspensi et horas indicantis*), that the experiment does not always succeed, and hence, he will not assert that the demon is always acting. The argument appears to be that, if the devil had it in hand, it would not fail. The pious and honest men aforesaid also protested that the phenomenon was natural and not due to fraud or fancy. "*Sed nondum persuaserunt*," pithily concludes Schott. The passage is noteworthy as containing a reference to the wonderful pendulum, which became, at a later day, the subject of scientific treatises, and still survives as a puzzle and amusement for children of all growths.

Sylvester Rattray (*Theatrum Sympatheticum*, 1662) believes in the sympathy of vegetables with minerals. According to him, the hazel is suitable for the discovery of silver, wild pine for lead, olive and palm for gold and silver.

It was in 1666 that Robert Boyle put the question, as member of the Royal Society of London, whether the divining-rod is really moved by the proximity of metal—a pertinent inquiry, which no one seems to have answered by authoritative and thorough experiments, unless we may accept as sufficient those of Kircher above mentioned. The accumulation of contradictory testimony from witnesses of all degrees of competency went on.

Matthias Willenius, a German author, published in 1671 or 1672 a book called *A True Account of the Rod of Mercury*, in which, as the title indicates, he appealed to astrology for the partial explanation of his theme, asserting that the influence of the stars under which the operator is born contributes to the turning of the rod over metals, "by the effect of the harmony established between heaven and earth."

Frommann (*Tractatus de Fascinatione*, 1674), says that, after long hesitation, he has decided that the use of the rod is lawful.

The Jesuit father, Dechales (*De Fontibus Naturalibus*, 1674), inclines to the same opinion, and speaks of the hazel as having been in all times (*omni tempore*) used as an index to springs. This is a curious illustration of the rapidity with which a tradition may come to be considered immemorial. In fact, if we except the striking of the rock in the desert by Moses—which is certainly not a case in point—the first trace of the use of the rod for discovering springs is in the works of the Beausoleils, scarcely fifty years before Dechales wrote his treatise.

Le Royer, a lawyer of Rouen, published in 1674 his *Traité du Bâton universel*, and in 1677 his *Traité des Influences et des Vertus occultes des Etres terrestres*. He declares that the rod by its sympathetic virtue can discover all hidden objects, metals, springs, etc. But he ascribes to it no moral power.

The Abbé Hirnhaïn (*De Typho Generis Humani, sive Scientiarum Humanarum Inani ac Ventoso Humore*, etc., 1676), while scoffing at many reviewed beliefs, admits without question the efficacy of the divining-rod.

St. Romain (*La Science naturelle degagée des Chimères de l'Ecole*, 1679) was one of the first believers in the rod to reject the sympathies and antipathies and to substitute the Cartesian corpuscular hypothesis—of which I shall have more to say hereafter.

Finally, the celebrated botanist, Ray (*Histoire des Plantes*, 1686), classed the divining-rod among superstitions.

This review of the literature of the subject has brought us to the end of an important period, namely, that in which the physical effects of the rod were exclusively discussed, its earlier uses for general divination having gone out of fashion and recollection. Indeed, any attempt to maintain these would have incurred the censure of the church, which would have settled at once the vexed question of agency by denouncing this unauthorized intrusion upon its spiritual prerogative as diabolic. This is indeed what speedily happened, as we shall see. The lost doctrine of moral power reappeared, not among the learned, but out of the obscure mass of the people. In the province of Dauphiny, in the south of France, the practice of the divining-rod, introduced perhaps by the Beausoleils, had become, fifty years after their death, an art followed by many experts, who were called *Hommes à Baguette*. They were employed to find springs of water, hidden treasure, mines, etc., and also to detect criminals, and even to settle disputes as to boundaries when the landmarks were gone. Two farmers, for instance, having a dispute as to the boundary between their farms, instead of going to a lawyer or judge, would send for a diviner. He, walking over the disputed ground, would indicate by the dipping of his rod the spot where the old landmark formerly stood; and this decision was accepted without appeal. Considering the expense of litigation in all times, and the peculiar character of the justice which at that time was sold so dear and worth so little, we may fairly say that, whatever be the merits of the divining-rod, the peasants of Dauphiny acted wisely in employing it.

In 1692, a mysterious murder was committed at Lyons. A wine-merchant and his wife were found dead, lying in their cellar near the bloody ax with which they had been slain. A neighbor urged the authorities (who seem to have had no clue to the murderers) to employ a rich peasant of Dauphiny, already famous as an expert with the divining-rod. This man, Jacques Aymar by name, was sent for—or rather it was not necessary to send for him, since he proved to be already on hand in the city, by the time it was decided to engage his services. This fact is significant, as giving the key to what turned out to be an extraordinary piece of clever detective work. A careful analysis of the numerous official and other records of this case show it to be quite possible that the diviner had obtained important clues before he was publicly set to work. He first demanded to be taken to the scene of the crime that he might get his "impression." This consisted in a sort of shuddering, accompanied with signs of agitation, pain, and exhaustion, and manifesting itself besides in the dipping of his rod. This took place at the spot where the bodies had lain, the spot where the ax was found, and also in the shop above, at various points which he declared to have been occupied or touched by the criminals. Having thus obtained a thorough impression, after the fashion of a bloodhound getting a scent, he started, though it was night, and followed with his rod the alleged course of the fugitives, passing without hesitation through many unlikely places, as far as one of the gates of the city. Next morning, he resumed the trail, and tracked it to the house of a gardener, where he declared that the criminals, either two or three in number, had stopped. The gardener and his wife denied all knowledge of them, and Aymar, consulting his rod, declared that neither had touched the murderer. But the rod dipped violently over two young children of the house, who thereupon confessed that three men had stopped there the day before, and had drunk wine at a table, which, by the way, had also been indicated by the rod. The children said they had kept this a secret, because they feared being punished for leaving the door unlocked while their parents were away. After some further delays and preliminary tests, the magistrates determined to let Aymar pursue the murderers. He declared that they had taken a boat down the Rhone, and he followed them with an escort in the same manner, landing from time to time at different points where he said they had stopped. His pursuit was continued for a number of days with various interruptions, the assigned causes of which seem to have been sometimes but pretexts, and permit the suspicion that the intervals were employed by him in getting information in other ways. However this may be, he finally brought up at the prison of Beaucoire, and after applying his rod in succession to the inmates, pointed out as one of the Lyons murderers a hunchback, recently arrested for larceny. This man, being taken back to Lyons, was recognized at several points on the road as having passed just after the murder, and finally, frightened by the accumulated evidence against him, made a full confession, and was subsequently broken alive. The other two murderers Aymar professed to follow to the sea, and at sea along the coast, until, as he alleged, they escaped from the kingdom.

So long as there was no doubt of Aymar's sincerity, this discovery of the criminal by the aid of the divining-rod seemed indeed marvelous. But it is not more wonderful than many detective operations in which the rod has played no part; and it is easy to trace the possible or probable methods which he employed. If, for instance, during the period just preceding his engagement by the magistrates, he had, in coming to town from his residence, fourteen leagues distant, or in hanging about the town, where every body was talking of the crime, picked up in any way the circumstances of the three fugitives entering the house where the children were, it is almost inevitable that he would have obtained also some general description of their appearance, and I need scarcely remark that the subsequent tracking of a hunchback would be no very difficult matter. It should be added here that the judges who sentenced the hunchback explicitly declared that they attached no weight to the indications of the rod as direct evidence of his guilt, but condemned him wholly upon his own confession, confirmed by abundant circumstantial evidence.

But this achievement of the rod, attested as it was by official records and by the public confession and execution of the criminal, made a great sensation in France; and Aymar was called to Paris, where both the court and the *savants* interested themselves greatly in his mysterious powers. Many marvelous feats are reported of him there; but the shrewd and rigorous experiments of the Prince de Condé exposed the emptiness of his pretensions. It was Aymar's claim that his rod was sensitive to the particular object which he was at the time seeking. When he sought a given murderer, the track of some other murderer would not divert it. When he was pursuing a criminal, he could not be led astray by subterranean water or treasure. If he felt these things in passing, his feeling was nevertheless distinguishable from that connected with his intention, etc. He could, at will, seek any given object, and, when doing so, could not be deceived. Unfortunately for this claim, the tests of the prince deceived him very often. For instance, a purse of money was shown him, and after he had got his "impression" of it, it was taken out to be buried in the garden, but, instead of burying it, the person who had it kept it in his pocket. Aymar proceeded to the garden, and, undisturbed by the immediate neighborhood of the money in the pocket of a bystander, located the spot where he said it was buried. In another case, he detected the gold of the gilding of a chair which was covered so as to permit a glimpse of its ornaments; but he sat on a similar chair, and walked through a saloon containing many of them, all completely covered, without discovering any gold. In another case, a window was designedly broken in a palace. Aymar was sent for to trace the thief, who, he was informed, had recently stolen some money from the palace. His rod promptly indicated the broken window

Digitized by Google

as the road by which the thief had entered, and he proceeded to trace also the route of flight, although no such theft had ever occurred. But so long as these and similar failures were not made generally public, Aymar continued to enjoy much celebrity, and no doubt it was enough to turn the head of a peasant to be the object of such attention. Growing more audacious, he undertook to reveal character with his rod, and on one occasion, having received a fee from a gentleman of the court, with the request that he would discover whether the gentleman's sweetheart was true to him, he sent for the lady's servant, and demanded of him another fee as a condition of certifying her virtue. Scandals of this kind became so bad that the Prince de Condé publicly exposed Aymar, and he returned to his home. On the way, however, in passing through a village, he took occasion to designate five or six of the most respectable houses as the abodes of wicked women, which made a great uproar. I wish I could say that nothing more was afterward heard of him; but unfortunately, it appears that, as late as 1703, this man was employed during the civil war to point out with his divining-rod Protestants for massacre, under the plea of punishment for crimes they had committed.

We find connected with the exploits of Jacques Aymar a new theoretical explanation of the divining-rod. Many persons of more or less scientific training, not doubting the honesty of the man and the genuineness of the sensations which he manifested, cross-questioned him on the subject, and thus accumulated a mass of supposed data for the formulation of the natural law underlying these phenomena. It was at this time that the Cartesian philosophy was dominant in France, and the "subtle matter," "corpuscles," "animal spirits," and "vortices" of Descartes furnished convenient hypotheses to explain almost any thing. The two doctors of Lyons first supplied such hypotheses to the case of Aymar; but the subject was treated at still greater length by the Abbé de Vallemont, in his treatise on the divining-rod entitled *Physique Occulte*, and published in 1693. In this work, he declares that by insensible transpiration particles escape continually from our bodies; that such particles pursue a vertical direction, and strike the divining-rod, which is thus caused to move up and down, assuming a line parallel to the path of the corpuscles. The holder of the rod receives corpuscular effluvia from other human bodies, and various substances, and communicates them through his pores to the rod, thus producing also a movement of revolution. The difference of the skin in different people results in various degrees of susceptibility to particular impressions; but Aymar was, according to the abbé, possessed of an epidermis which could receive all kinds of impressions without confounding them. The abbé says that there is a difference of form among the corpuscular effluvia of springs, minerals, bodies of thieves, those of assassins, those of naughty women, those of landmarks, etc., etc.; in other words, he recognizes the existence of aqueous matter, larcenous matter, murderous matter, etc., and the last-named variety was the only one which produced upon Aymar very painful impressions. This was due, according to his scientific expounder, to the vehemence of remorse which pervades the corpuscles of an assassin. The fact asserted by Aymar that he had detected and followed the trail of a murderer twenty-five years after the murder, and the fact that in almost every instance he necessarily began his researches a day or two after the crime—to say nothing of the cases in which he determined the locality of the landmarks which had been missing for an immemorial period, forced the abbé to a wild hypothesis of the extraordinary levity of the corpuscles, by virtue of which they remained a long time suspended in the air in spite of rain, wind, and even other corpuscles of later origin.

Father Lebrun, in a pamphlet on *The Illusions of Philosophers concerning the Divining-Rod*, printed at Paris in 1693, seriously refuted the system of Vallemont. This pamphlet was republished in the third volume of Lebrun's *Critical History of Superstitious Practices* (Paris, 1702).

But Father Lebrun and a large proportion of those who took part in the discussion rejected the scientific theory altogether and attributed the facts to Satan. It was asserted that not only wicked people might obtain the divining power by a league with the devil, but that such an alliance might be made unconsciously and that the power might be conferred upon an unwilling subject as a means of ruin to his soul. Several cases are described at length in which persons in whose hands the divining-rod pointed out springs, etc., had been, by prayer and fasting and the help of their spiritual advisers, delivered from this dangerous gift. The authorities of the church favored this view, at least so far as any moral uses of the divining-rod were concerned. In 1701, the Inquisition of Rome condemned the divining-rod and all writings in support of it.

I condense from M. Chevreul's book the following list of the principal authors on the subject, for the period now under consideration:

Dr. Chauvin, of Lyons (a letter to the Marquise de Senozan, dated September 22d, 1692, published in the brochure *Superstitions anciennes et modernes*, Amsterdam, 1733; also in an appendix to the second edition of Lebrun's *Histoire critique des Pratiques superstitieuses*).

Dr. Pierre Garnier, of Lyons (a letter to M. de Sève, published November 10th, 1692, at Lyons). This, like the letter of Dr. Chauvin, advanced the corpuscular hypothesis.

Two anonymous letters concerning the divining-rod, published in the *Mercure* of January and February, 1693. The first combats the corpuscular hypothesis; the second argues that, although this explanation is to be rejected, there is, nevertheless, nothing supernatural, magical, or diabolic about the phenomena, and they are probably to be referred to physical causes as yet unknown.

M. de Couriers, a blind man and thorough partisan of the divining-rod (a letter in the *Mercure* of March, 1693).

M. L. de Vallemont, priest and doctor of theology (*Physique occulte, ou Traité de la Baguette divinatoire et de son Utilité pour la découverte des Sources d'Eau, des Minières, des Trésors cachés, des Voleurs, et des Meurtriers fugitifs*, Paris, 1693, 12mo, 608 pages). The argument of this book has been summarized above. Its purpose was to diminish the category of "occult" things by showing that the phenomena of the rod, like those of magnetism and electricity, were explicable by the physical corpuscular hypothesis.

Two letters published in the *Mercure* for April, 1693, by order of the Prince de Condé. One is anonymous; the other is addressed by M. Robert, *procureur du roi*, to Father de Chevigny. These are the documents which record the failures of Aymar; and the second concludes as follows: "His Serene Highness desires the assurance to be given to undeceive the public that the rod of J. Aymar is nothing but an illusion and a chimerical invention. These are the prince's words."

Father Lebrun (*Lettres qui découvrent l'Illusion des Philosophes sur la Baguettes, et qui détruisent leurs Systèmes*, Paris, 1693; also *Histoire critique des Pratiques superstitieuses qui ont seduit les Peuples et embarrassé les Savants*, Rouen and Paris, 1702). These publications have been alluded to above. The letters comprise an interesting correspondence among Father Lebrun and three of the foremost *savants* of France, Father Malebranche, the Abbé de Rancé (the celebrated Abbé de la Trappe), and the Abbé Pirot, Chancellor of the University of Paris. Lebrun (writing before the Lyons murders) narrates the alleged powers and performances of the diviners of Dauphiny, and asks Malebranche what he thinks of the matter. The latter, reasoning acutely on the data offered, decides that, as to physical objects (for example, springs), if the action of the rod is real, water on the surface must agitate it more powerfully than water underground, also that it can not be possible by any natural law to distinguish between the action of a small spring near the surface and a larger spring lying deeper. As to moral effects (discovery of murderers, missing landmarks, etc.), he concludes that, if the rod really does this without fraud, it can only be from a supernatural cause (presumably demoniac), and that the use of the rod is therefore to be condemned. Lebrun rejoins, agreeing with this view as to the moral effects, but suggesting the corpuscular hypothesis as to material objects. A second letter of Malebranche declines to yield this point, and positively ascribes the whole thing to the devil. Meanwhile, the Abbé de la Trappe consulted by Malebranche, and (like the latter) assuming for the sake of the argument, but not accepting fully the reality of the phenomena, says the discovery of murders, etc., must be ascribed to Satan, but the physical effects may be the result of a physical cause. Nevertheless, the use of the divining-rod should be discouraged altogether on religious grounds. Chancellor Pirot takes the same position, saying that the curés should forbid this practice as unlawful.

In his *Histoire Critique*, Father Lebrun gives a large number of instances in which the divining-rod has failed. He cites the provost of the Isle of France, who testified that he had often employed experts with the rod, both to detect criminals and to discover springs, and had never found one in whose hands the instrument was not "often variable and very often false." He shows the fundamental contradiction between two schools of practitioners, one of which declared that touching the rod with the same substance as the hidden substance which was causing it to move would stop the motion; while the other declared that this proceeding argumented the motion. The conclusion of the argument is, that the phenomena of the rod (which Father Lebrun appears to believe are sometimes free from conscious imposture) are due to an intelligent cause of some kind, and that this cause must be satanic.

Father Ménestrier (*Indications de la Baguette pour découvrir les Sources d'Eau, les Métaux cachés, les Vols, les Bornes déplacées, les Assassinats*, etc., published at the end of the author's *Philosophie des Images énigmatiques*, Lyons, 1694). This author takes the same view as the preceding.

M. Baritel (*La Verge de Jacob, ou l'Art de trouver des Trésors*, 1693). The translation of this book by Thomas Welton has been already mentioned. The author appears to hold the corpuscular theory of the Abbé Vallemont, with the addition (which I do not find in any of the views of Vallemont's book), that he ascribes the capacity of different men in the use of the rod to the effect of the planets under which they were born, and defines this effect to consist in opening the pores of some more than others, and filling some more than others with "active particles," which, being crowded out through the aforesaid open pores by the intrusion of exterior particles (from springs, metals, murderers, stolen goods, boundary lines, etc.), powerfully affect the rod. Whoever has from his favorable stars both particles and pores galore, can discover with the rod any thing he reasonably seeks. But he who has "only plentitude of particles with closed pores," will be sensitive to certain things only, to wit, such as move him most strongly, because the particles emanating from them violently eject *his* interior particles in spite of his less abundantly perforated epidermis.

The condemnation expressed by so many ecclesiastical authorities and by the Inquisition (October 26th, 1701) undoubtedly checked the use of the divining-rod for moral purposes. At least, we hear little of such applications in the eighteenth century. But believers in the rod were still numerous, and practitioners abounded, particularly in Dauphiny. The discoveries of Galvani put into the hands of the crude science of the day the materials for a new hypothesis, which was first applied to the so-called hydroscopes or water-diviners. One of the most celebrated of these, Bartholemy Bleton, was born in Dauphiny in 1750, and in 1780 was called to Lorraine by Dr. Thouvenel, who wished to study a good specimen of this art. The doctor, like his predecessors a hundred years before, tried credulous experiments and asked questions in abundance, and obtained a mass of supposed facts, out of which he immediately made a book, published in 1781, and called *Mémoire physique et medicinal montrant des Rapports évidents entre les Phénomènes de la Baguette divinatoire du Magnetism et de l'Electricité*. It would be useless to give the voluminous details of his investigation. The following points are, however, especially noteworthy. In the first place, Bleton apparently did not profess to discover immaterial qualities or facts, but chiefly confined himself to the detection of running water. In the second place, he frankly avowed that the rod possessed no power in itself by virtue of its form or material, and that it was merely an index, outwardly exhibiting to the spectators his inward feeling. This feeling the doctor declared to be a tremor, attacking first the diaphragm and communicating itself through the body and hands to the rod. In the third place, this tremor was found by Dr. Thouvenel to be weakened, though not destroyed, when Bleton was on a tree or ladder or another person's shoulder, instead of the ground, or when he touched electrified substances; but the tremor and also the movement of the rod were completely stopped when Bleton was insulated from the ground. Upon facts of this kind he based his electrical theory. I remark, by the way, that the observations and the theory of Mr. Latimer, in his recent work on the divining-rod, already mentioned, recall in a striking manner the performances of Bleton and the theory of Thouvenel. Mr. Latimer claims to have made the new discovery that the effect of the divining-rod is destroyed by insulating the

Digitized by Google

practitioner, as, for instance, by placing him upon a platform supported by glass bottles. If he had known how thoroughly this claim had been examined and refuted, almost exactly one hundred years ago, he would have had less faith in its novelty and value.

Thouvenel's book made no little sensation, and in 1782 Bleton was called to Paris, where a remarkable series of experimental tests were applied to him. A newspaper report of the day declares that, in the presence of many thousands of spectators, he followed a subterranean aqueduct in the garden of the Luxembourg for fifteen thousand yards without a mistake. The chief-engineer of the water-works is reported to have said that the trace was so accurate that, if the maps of his office had been lost, Bleton's footsteps would have constituted a complete survey to replace them. It is just possible that the *Journal de Paris* was tempted to make a sensation of this case, and it is also quite possible that a keen observer might notice indications other than those of his own diaphragm, by which he could follow the line of buried pipes. A large number of experiments, more calmly reported, certainly do not sustain the enthusiasm of this account. It was found, for instance, that Bleton often passed over running water, when blindfold, without noticing it; and that when taken several times over the same course, he would not point out accurately each time the spots which he had previously marked. For example, of sixteen points once indicated, he recognized with the rod on the second round but eight, and missed the other eight. A single point to which he was repeatedly brought blindfold, he indicated three times and missed three times. Of seven channels of running water which he was made to cross repeatedly, he indicated one once in four times, another once in four times, and another once in three times, while still another, which he crossed in two spots, affected his diaphragm at one crossing, and not at all at the other. The insulation experiment was repeated by a physician at Paris. As a point where Bleton's rod was powerfully affected by alleged subterranean water, he was mounted upon a stool with glass legs, and immediately the rod ceased to be affected. When the stool was removed, however, and he stood upon the ground, the rod resumed its sensitiveness. But Dr. Charles, who conducted this experiment, took occasion, while Bleton stood upon the stool, to bring the top, without his knowledge, into electrical communication with the earth by means of a good conductor, thus destroying the insulation completely, though the hydroscopist supposed it still to exist. Under these circumstances, the rod remained inactive, and the destruction of insulation did not produce the slightest result. This was declared at the time to be a proof of Bleton's charlatanry; but, as we shall see hereafter, it is equally consistent with the hypothesis of unconscious mental and muscular action.

As a final test of Bleton's capacity as a hydroscopist, he was taken blindfold into the new church of St. Genevieve, where there was known to be no water for one hundred feet below the floor, the vaults, foundations, etc., actually extending all that distance below. Here he professed to discover at numerous points large and small streams of water. Thouvenel subsequently asserted that his *protegé* had been affected by currents of damp air circulating in the cellar; but this explanation was universally considered as a desperate attempt to maintain a theory already brought into discredit by experimental tests. Bleton, however, though he ceased to be seriously respected by impartial scientists, continued to receive much attention, and to do a thriving business, both in Paris and subsequently in the provinces. Here, however, he no longer worked blindfold, or professed to see with his diaphragm. He proceeded, like the ordinary water-diviners, with open eyes, studying all the natural indications, and coming to his decisions with abundant leisure; and under these circumstances it is beyond doubt that he rendered many valuable services to landed proprietors by successfully locating wells. In many cases, however, he failed entirely, and it is reported that, even in those in which he succeeded, he was seldom right as to the depth at which water would be found or the quantity which would be obtained. It should be mentioned that in Dauphiny, where Bleton discovered a large number of springs, he was regarded with an esteem never given to Aymar and some other famous hydroscopists. In other words, the people who knew most about the art of discovering water pronounced Bleton to be a real expert, while they believed Aymar and Parangue (of whom a word presently) to be more or less charlatans. A review of all the facts leaves little doubt that in Bleton's case there was an unusually large proportion of the skill of the prospector, combined with rather less than usual of the mysterious claims of the wizard.

Concerning Jean Jacques Parangué, mentioned above, it will be sufficient to say that he was born in 1760, near Marseilles, was said to have been peculiarly sensitive as a child to the presence of subterranean waters, and became famous as a hydroscopist; but he used no rod at all, and the scientific theory advanced by his friends was one of clairvoyance. His eyes was described as very peculiar, and it was asserted that he saw water through rocks, earth, or masonry, but, strangely enough, not through wood, crystal, or glass. Like Bleton, he often deceived himself as to the volume and depths of the springs he discovered.

Dr. Thouvenel never saw Parangue, but defended him against the incredulity of the physicists, and undertook to show that the phenomena of clairvoyance even was merely a case under his electrical theory. According to his explanation, the delicate nerves of the eyes were affected by the electrical currents traversing the body, and therefore the clairvoyant really experienced the sensation of vision by an internal, not an external excitation. Those who have read the admirable treatise of the late Dr. Clarke upon *Pseudopia* will notice with interest that in this case Dr. Thouvenel, explaining imaginary facts by an untenable hypothesis, nevertheless came very near a true physical theory of visions.

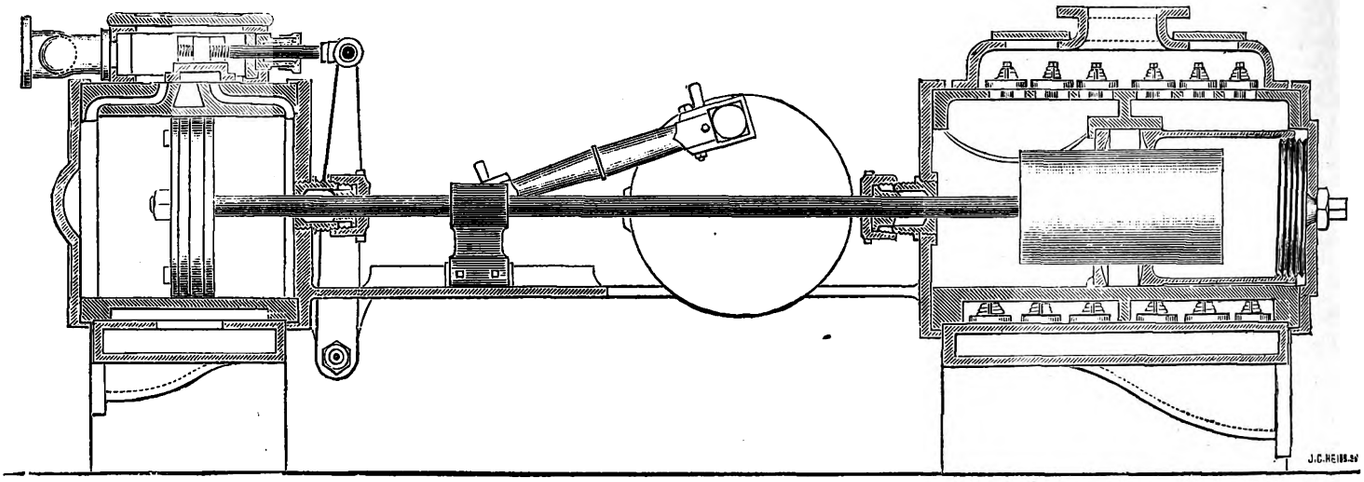
The worthy doctor emigrated at the time of the French revolution, and carried with him to Italy another Dauphinese hydroscope named Pennet, whom he exhibited from city to city in support of his electrical theory. Pennet professed to find with his rod not only water, but buried metals and coal. I will not go at any length into the experiments. Some of them were striking and successful, and impressed even such *savants* as Spallanzani, more or less predisposed to expect discoveries in the new domain of animal magnetism. In many other cases, however, the experiments failed. For instance, in a trial of three days, at Padua, before a commission of *savants*, Pennet promenaded for two hours on the first day in a garden in which had been buried at different points four metallic masses and a thousand pounds of coal. He could not find the metals at all, and only after much difficulty indicated the coal. On the second day, his ill success was equally marked. Finally, on the third day, of three metallic deposits, he failed to find the first, came pretty near the second without exactly hitting it, and found the third. The area covered by the search was only eight hundred and forty square feet. Upon this test, Spallanzani revoked his favorable opinion. But at Flor ence, as reported by M. Bilot (*Mélanges Scientifiques et Litteraires*, 1857, tome ii., p. 80), though I do not know on what authority, Pennet was so completely disgraced as to render worthless all evidence furnished by his career. A walled inclosure was prepared for experiment. It contained ninety small divisions, in five of which metals had been hidden. Dr. Thouvenel having discovered that wet weather hindered success, the experiment was delayed until after eight dry fine days, and it was then fixed for the following day. During the night which intervened, Pennet climbed by means of a ladder into the inclosure. A suspicious person who was watching the ground removed the ladder, and whatever the divining-rod could show, it was unable to show the prisoner the way out. This adventure, being made public, destroyed the credit of Pennet at Florence. Dr. Thouvenel could not deny the fatal fact, but, with true loyalty to science, declared that Pennet's moral defects had nothing to do with his physical faculty. It is only fair to add that no such passage as this is cited from Dr. Thouvenel's works.

(TO BE CONTINUED.)

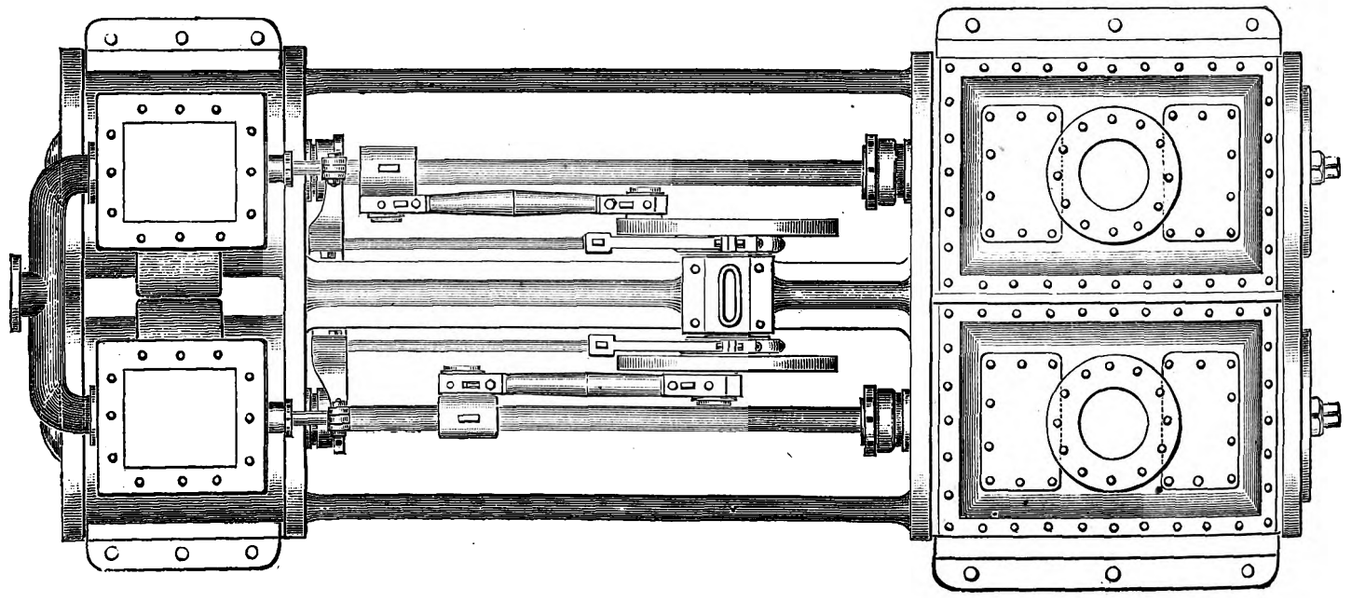
SOME TESTS FOR THE EVAPORATION OF THE HORIZONTAL STEAM-BOILER

Prof. Henry Morton, of the Stevens Institute of Technology, Hoboken, N. J., has been making some tests for the evaporation of the horizontal steam-boiler, in order to ascertain what the efficiency is. His trials so far have demonstrated that the usually rated 50 horse-power horizontal boiler, with a heating surface of 850 square feet, and 24 feet grate surface, will be 9·25 pounds of water per hour with a bituminous coal containing 16 per cent of refuse matter, from the temperature of 212 degrees feed-water, with a rate of combustion of ten pounds of coal per square foot of grate surface per hour, or 11·04 pounds of water per pound of combustible, the temperature in the chimney being 375 degrees Fahr. The tests are not complete, and are to be carried on further, when a fuller report will be made. A very extended trial is to be had, which will include natural and forced draught and the various other circumstances under which the boiler may or might work.

THE STRENGTH OF WIRE ROPES.



Winding-ropes when in use stretch from 4 to 1 per cent of their entire length, without impairing their strength. This usually takes place during the first six months of working; but while this lengthening process is going on, if the wires are not twisted to the same extent, considerably more strain will be put on some than others; therefore to mitigate this, the strands are wound around a central core of hemp, as ropes with wire *centers* have not given satisfactory results in practice, although a greater breaking strain is obtained with a relatively smaller rope. The same may be said of iron centers. These will not stretch and accommodate themselves to the elongated strands; consequently, the center is liable to break and spoil the rope. In the case of hemp centers, they stretch with the strands and also allow the wires to bed themselves with more solidity. To provide for the stretching of the ropes, large links are put between the detaching-hook and cap. These are kept in sets of 1, 2, 3, and 4, so that if the rope had stretched 1¼ feet, and 4 links were in, these would be replaced by a set of two. When all the links have been removed in this way, then an additional coil will have to be put round the drum-shaft if the rope requires further shortening. Sometimes *strands* are made with eight or more wires wound around a hemp core, but are not recommended, except in the case of wet pits, with galvanized steel wires; in this way they have been found to answer very well, as they do not corrode. For ordinary work, experience demonstrates that ropes are best made with hemp *centers* only, which should be hard and well rounded up. Six strands of nineteen wires each make the most durable ropes. These work better than one composed of six or seven wires in a strand, as the latter, being larger and less pliable, are more likely to snap in bending around wheels and drums. When three of four of these large wires break near together, the rope is hardly fit for work, whereas the breakage of that number of small wires would be of little consequence. The small wires last a long time, as there is not much friction where large pulleys are used, and the inside wires are not affected by it at all. However large the wire may be, the least wear on the outer surface weakens it considerably. At the same time, a strand of seven wires, equal in size, is nearly perfect, each touching its neighbor, and also the center one. Six strands in a rope are better than four or five, as they make it rounder, and consequently the friction is better distributed.



A COKE-BURNING LOCOMOTIVE.—Several experienced Western mechanical engineers visited Philadelphia recently, to inspect the new locomotives of the Reading Railroad. One of these engines was prominently brought into notice by its performance on the Chicago, Burlington & Quincy Railroad during the Chicago Exhibition, and afterward on the Baltimore & Ohio Railroad. Particular interest attaches to the capacity of the locomotive to use coke for fuel, as that combustible, being entirely free from smoke, will not only at once relieve the Western companies from the penalties for infractions of the laws for the prevention of the smoke nuisance, but will secure greater comfort and pleasure to the traveling public. The tests of the locomotive demonstrated that continuous runs of two hundred miles can be made with coke fuel, without any further attention on the part of the fireman than simply feeding the furnace, and that meanwhile no clinker or other obstruction to the draught occurred during the trials, which were of a most exacting nature. The coke used was the product of the Connellsville Coke and Iron Company, and its chlorific efficiency was found to be in excess of seven pounds of water evaporated for each pound of coke consumed. At the request of the visiting experts, further evaporated tests of the same kind of fuel are to be made in one of these locomotives.

THE HENWOOD DOUBLE-ACTING PUMP.

As the result of twenty years' experience in the building of mine and quarry machinery, Messrs. Henwood, Whitaker & Co., of Philadelphia, have recently brought out a new design of double and direct-acting steam plunger pump which has a number of features of special merit. Our illustrations will aid in fully explaining their character and scope. With a view to overcoming the trouble and expense incident to the wearing of cylinders and metallic packing rings, especially when dirty or gritty water is handled, the pump proper is made as follows: The plunger has no metallic contact, but works through hemp or elastic packing in the internal stuffing-box shown in the accompanying vertical section. The packing may be compressed at will about the plunger by a movement of the cage, the back end of which screws upon a brass junk ring threaded on the outside. Fastened to the junk ring is a wrought-iron stem which passes through

the pump cylinder-head and ends in a square bolt. After loosening the lock-nut, a wrench may be applied, the junk ring be turned, and thus the cage with its annular end be forced forward, compressing the packing. We are informed that the packing will last from one to six months, according to the character of the water and the duty required, and then the replacing of three rings of hemp requires only ten minutes' time. The water-ways are large and direct, as will be seen, thus giving free passage to sand and mud. In a number of tests made under unfavorable circumstances, the pump discharged from 30 to 35 per cent of river sand.

The plain steam valves are made with the necessary lap to expand the steam from 15 to 40 per cent, so that to a great extent the advantages of compound pumps are secured, without sacrificing simplicity. The slide-valve is worked by a lever which gets its motion from the eccentric, which has one half the throw of the valve, thus giving an advantage in the smaller sizes of pumps, where the eccentric is placed on the circumference of the crank-wheel. The engines are geared at right angles, the cross-heads being attached directly to the connecting-rods and piston-rods and working on guides as shown in the drawing. Being a crank-pump, it has a positive motion and positive length of stroke through all variations of speed. The suction and steam exhaust pipes are placed beneath the pump, thus making every thing free and clear about the pump.

HIGH SPEED IN ENGINEERING.

Mr. Percy Westmacott, President of the British Institution of Mechanical Engineers, in his annual address before the recent Liége meeting, made the following interesting remarks: There is a proverb, "More haste, less speed," but this, though true of human labor, which ceases to be accurate when forced beyond a certain rate, does not hold good of mechanical processes. Generally, it may be said that rapidity of working not only reduces cost, but improves the result, and also confers great benefits from the way in which it brings out and perfects the highest qualities of the engineer. To be able to do a thing leisurely and quietly, simply requires the rudest materials and the rudest workmanship; but if the work is to be done quickly, or the appliances made to move quickly, the case alters. Mechanical energy increases as the square of the speed; and so it may be said that the mental energy and skill required to carry on work increase also at something like the square of the speed with which that work is performed. The materials used must be far stronger and far finer; every thing must be well proportioned and balanced; there must be the most perfect arrangement in each structure and in every part of a structure; the most perfect workmanship in the fitting of these parts together; and thus we may almost reverse the proverb, and say of mechanical processes, "The higher the speed, the better the work."

This view opens out so wide a field for contemplation that to traverse it even rapidly would require rather a volume than a paper. All that can be done at present is to give a very few obvious illustrations of the subject. Take, for instance, the steamship with her engines and accessories, more especially the modern ship of war. There is scarcely any structure which requires so much care and skill, both in its design and execution. Not only does it involve all the problems which occur in erecting steam machinery on land, but in addition the vessel has to contend against the heavy and uncertain strains due to wave action during the roughest weather. Hence all parts of the structure, and especially the engines and boilers, should be so designed and constructed, and the materials so selected, that their weight may be reduced to the lowest point. Every increment of speed attempted to be given is accompanied with complex questions of increasing difficulty, taxing the skill and power of the engineer to the uttermost. The development of the compound condensing engine, for instance, is largely due to the marine engineer, who was

Digitized by Google

driven by necessity to study most closely the economy of fuel, in order thereby to gain speed.

The torpedo-boat is an excellent example of the advance toward high speeds, and shows what can be accomplished by studying lightness and strength in combination. In running at 22½ knots an hour, an engine with cylinders of 16-inch stroke will make 480 revolutions per minute, which gives 1280 feet per minute for piston speed; and it is remarked that engines running at that high rate work much more smoothly than at slower speeds, and that the difficulty of lubrication diminishes as the speed increases: doubtless the experiments on friction which are now conducting by this institution will throw light upon this subject.

An important experiment in high speed in light vessels, which will doubtless be watched with much interest, is now carrying out. Mr. Loftus Perkins is building a steel vessel with a screw at each end. She is 150 feet long; her boiler pressure will be about 800 pounds per square inch, and she has a four-cylinder compound condensing engine of 800 horse-power working on to a single crank, and making from 400 to 500 revolutions per minute. When this vessel is laden with 300 passengers, her total weight will not much exceed 150 tons. Should this experiment be successful, it will materially advance the solution of the problem, how to put the largest possible amount of propelling power into a vessel, and so to drive her at the highest possible speed.

Again, in touching upon speeds, the mind naturally reverts to railroad traveling. Here, however, it would seem as if, for the present, we had reached a maximum. It is surprising how soon the speed of the locomotive was brought up to something approaching its present limit. George Stephenson was laughed at in 1825 for maintaining that trains would be drawn by a locomotive at twelve miles an hour; but the Rocket herself attained a speed of twenty-nine miles an hour at the Rainhill competition, in 1829, and long afterward ran four miles in four and a half minutes. In 1834, the average speed of trains on the Liverpool & Manchester Railroad was twenty miles an hour. But by 1840, there were engines on the Great Western Railroad capable of running fifty miles an hour with a train, and eighty miles an hour without. In 1841, we find Stephenson himself ranged on the side of caution, and suggesting that forty miles an hour should be the highest regular speed for trains. Now, it is a remarkable fact that the highest speed at which locomotives run in ordinary practice scarcely seems to have been raised during the last twenty-five years; on the other hand, the weight of the trains has been perhaps doubled. Although the average running time of express trains has in many cases been improved, this has been almost entirely due to their making fewer stoppages. At the same time, the speed occasionally attained is very great. Engines on some of our principal lines have repeatedly run fifteen miles in twelve minutes, or at a speed of seventy-five miles an hour, and express trains run regularly at fifty-three miles an hour. It does not follow, however, that there is never to be any increase in the speed of trains, and it seems a point well worth consideration in what way the time of transit between important centers of trade can be shortened.

What are the causes which have tended to prevent any improvement in this particular? In the first place, it may be said that the permanent way would suffer seriously by further increase in speed; but this could surely be overcome in time by improving the permanent way itself, which also remains very much in the same condition and of the same construction as it was twenty-five years ago. Again, it may be said that the running at a higher speed would require more powerful engines, and hence that trains now worked by a single engine would require two, or would have to be split up into two trains, at a great increase in running expenses. This, however, assumes that it is not possible so to improve the engine that it shall be able to exert a considerably higher power without an inadmissible increase in weight. By utilizing a larger part of the total weight of the engine as adhesion weight, it would be easy to obtain the amount of adhesion required for the increased tractive force; and for this purpose Mr. Webb's compound locomotive (to be described by the author in a paper he has prepared for this meeting), which enables the number of driving-wheels to be increased without the use of coupling-rods, appears to merit particular attention.

Another point in which improvement may possibly arise in the future should be noticed. On the Russian railroads, where both coal and wood are dear, the burning of petroleum has now taken a practical form. Our member, Mr. Thomas Urquhart, has been very successful in this direction, and is now running locomotives regularly which use only petroleum refuse, and which show a marked economy over coal or wood. To test the point, he prepared three locomotives of exactly the same type, and started them on successive days under exactly similar conditions of weather, train, and section of road. The trips were made both ways, and the results per verst, including fuel required in lighting up, were as follows:

Anthracite, 52·9 Russian pounds, cost	26·35 copecks.
Wood, 0·0107 cubic sashin, cost	23·54 "
Petroleum refuse, 27·36 Russian pounds, cost	11·64 "

There is thus in this instance an economy of at least 50 per cent on the side of petroleum, the boiler pressure being from 120 pounds to 130 pounds, and the gross load over 400 tons. At the same time, the weight of fuel used, as against coal, is diminished by about 50 per cent, which is a most important item.

Although petroleum is scarcely a product of Western Europe, we have to notice on the other hand the progress which has lately been made in the extraction of oil as a waste product from coal, etc. Mr. Jameson has extracted as much as nine gallons per ton from mere shale. It is suggested that markets for such oil will be difficult to find; but it seems allowable to hazard the idea that we may hereafter see our locomotives, even in England, running with oil fuel, which would be at once much lighter and much more easily renewed than the coal which is used at present, and get rid of the intolerable nuisance of smoke and dirt. There might, in fact, be an oil-tank and a water-tank side by side at every stopping station, and the engine would replenish her store of fuel at the same time as her store of water.

For a special case, where speed is not only a means of doing work well, but an indispensable condition of doing the work at all, we may take the construction of long tunnels. As to this, we have the advantage of two very valuable papers on the St. Gothard Railroad, prepared by Herr Wendelstein, of Lucerne, one of them already published in our Proceedings, the other to be read at the present meeting. The piercing of a tunnel nine miles in length through the main chain of the Alps would be a financial if not a physical impossibility, but for the enormously increased speed of working which has been offered us by the invention of dynamite on the one hand and of rock-drilling machines on the other. As a result, we find that the St. Gothard Tunnel, nine miles long, was completed in nine years; while the Arlberg Tunnel, begun with the advantage of the St. Gothard experience, will be completed, it is confidently expected, at a rate 50 per cent quicker. As regards the driving of the leading heading (the crucial point in tunnel work), the rate at the Laveno Tunnel is stated to have reached 19 feet per diem. Even in the hard granite of the Pfaffensprüng on the St. Gothard, the rate of advance, with the Brandt hydraulic drill, reached a maximum in May, 1880, of 13 feet per diem. At the Arlberg Tunnel, I believe that still better results have since been attained with the same machine.

HISTORY OF THE IRON INDUSTRY IN THE LIEGE DISTRICT, BELGIUM.

By M. Edouard de Laveleye, of Liege.*

It is difficult to say exactly how the art of working iron originated in those provinces of ancient Belgium, which have since become known as the district of Liége. It is certain that Asia was the cradle of iron working, and it is possible that the Eburones and the Nervii, the ancestors of the present Belgians, brought with them from the Euxine, where they had their origin, secrets which had been already known for ages in that district. However this may be, it is almost certain that, when Cæsar arrived in Gaul, he found among the tribes he subjugated a knowledge of the art of transforming the ores of iron into a metal which they used for different purposes, especially that of arms. The discovery, in 1870, of ancient furnaces, still filled with materials, at Lustin, near Namur, enables us to understand the primitive method employed for the manufacture of iron. The furnace consisted of a single excavation in the ground, oval in form and rounded at the bottom; it was about twelve feet long by nine feet wide and three feet deep, and was formed in a bed of clay; a channel pierced through the clay allowed air to enter the bottom of the furnace. In this hollow was found the metal, which contained 93·48 per cent of iron, 0·37 of carbon, 4·94 of fusible materials, and 1·21 of sulphur and phosphorus. It is probable that the Romans communicated to the ancient Belgians the use of the bellows, which had long been known to them; and that other improvements were made during their rule in the art of treating iron ores. The invasion of the German tribes probably stopped the impulse given by the Romans to the manufacture of iron. In the eighth century, under Charlemagne, appeared the furnace) called the *borneau à masse*, or Stückofen, which was higher than the old furnaces, and thus allowed a greater concentration of heat. Between the eighth and the twelfth century, the iron trade developed considerably, and the metallurgist Karsten cites the Low Countries as the district where the manufacture of iron at that period had reached its highest perfection. From thence to the fifteenth century, the progress realized was small. In 1468, moreover, the iron-works of the Liége District were almost entirely destroyed by the troops of the Duke of Burgundy. It should be remarked that up to this time malleable iron was almost the only product; but Karsten who has been cited above, observes that the first apparatus for producing cast-iron was established in the Low Countries, whence the art extended into Sweden and England. The oldest blast-furnace appears to have been constructed near Namur, in 1340. It is, at any rate, certain that before 1400 the foundry pig blast-furnaces of Les Vennes and Grivegnée, near Liége, were well known. During the succeeding three centuries, the number of blast-furnaces grew so rapidly that in 1700 an edict of the Prince-Bishop of Liége forbade the erection of any new furnaces for the next twenty-five years. The use of coke as fuel for blast, was introduced from England at a relatively recent period. In 1769, an attempt to smelt iron ores by means of coke was made at Juslenville, near Spa, but without success. On the other hand, wood becoming scarce, raw coal had been used for the finishing of malleable iron as early as 1627; but its employment in the process of transforming cast-iron into malleable iron was also of foreign importation. This process became common in England while it was still unknown in Belgium. It was in 1784 that Cort and Partnell invented in England the puddling-furnace and grooved rolls. Those improvements were introduced into Belgium, but the French revolution shortly afterward put an end to all progress in industrial arts, and the works of the Liége District were in great measure reduced to a condition so deplorable that it was necessary to close them. There was, however, no long intermission of activity. In 1800, circular blast-furnaces were found to be replacing the octagonal furnace hitherto in use. Their hight was at the same time raised from 15 feet to 25 feet. In 1803, the casting of cannon was commenced at Liége, and soon became the largest industry of the province. The idea, however, was still general that the coal of Liége was not fit for making coke, and it was not until 1823 that an Englishman, whose name has become celebrated—John Cockerill—erected at Seraing the first blast-furnace, using coke as its fuel. This furnace remained unique of its kind until 1830; it was the origin of the works of the Cockerill Company, one of the most important on the continent. About the same time—in 1821—Michael Orban erected at Grivegnée the first puddling-furnace and the first rolling-mill on the English pattern. After 1830, the iron trade of Liége made a sudden start under the double influence of the introduction of railroads and the inauguration of large financial companies. In 1839, and afterward in 1848, serious crises occurred in the trade; but these reverses were succeeded on both occasions by new advances in prosperity. Hitherto, the only ores treated in Belgium had been those from the district of the Ourthe and that between the Sambre and the Meuse. These ores are now almost exhausted down to the level from which water could be pumped to give a profit, and the iron trade of Belgium could not have continued had not new raw material been brought into use. There exists in the Devonian formation an important bed of oligiste or specular ore, of an oolitic character; but for a long time this mineral was considered impossible to reduce. In 1853, however, the blast-furnaces of Ougrée produced a revolution in the Belgian iron trade

* Institution of Mechanical Engineers.

Digitized by Google

by succeeding in the utilization of these ores, and the trade then entered upon a new series of prosperous years. We may now proceed to the improvements introduced into blast-furnace working. In 1803, the bellows, which had been in use from the earliest times, began to be replaced by blowing-engines with metallic pistons; and in 1837, the Cockerill Works took the initiative in introducing the hot blast. It was the same works which introduced into Belgium the making of Bessemer steel. The first converters were erected in 1863. It is probable that the discovery of the cementation process for the making of steel had its origin in Liége. At the beginning of the seventeenth century, in 1613, a permission to convert iron into steel is found to have been officially accorded to two armorers of Maestricht, a town which then belonged to the province of Liége. Karsten is, therefore, right in saying, "England, which has now become the school of iron metallurgy, owes to the continent"—in fact, as we have said, to the district of Liége—"two great discoveries, namely, that of the blast-furnace and that of cemented steel." Our notice of the iron trade may be concluded by some details as to its situation at the present time. The discovery of the means of reducing the specular iron ores, at the time when the old ores were exhausted, saved the district from ruin. At this moment, however, the former ores in their turn are nearly exhausted, and the blast-furnaces are almost exclusively supplied, as far as pig-iron for puddling is concerned, from ores raised in the Grand-Duchy of Luxembourg, and, so far as steel pig is concerned, from ores raised in Spain. Thus, during the year 1882, the blast-furnaces consumed 394,405 tons of foreign ores, of which 182,842 tons came from Luxembourg, and 152,023 tons from Spain and Algeria. On the other hand, only 82,612 tons were indigenous ores. As a set-off to this disadvantage, the Belgian works are placed in the center of a district producing coke, which is cheap and of good quality. They are in a country where prices are in general favorable, where labor is abundant, and where workmen are skillful. The ores of Luxembourg are relatively poor in iron, and contain a good deal of phosphorus; but they fuse with great rapidity, inasmuch as they frequently contain a flux within themselves. They have gradually modified the nature of the Belgian trade. A restricted make of superior quality, has given place to a largely increased make, but no longer of so high a character. The tendency at this moment is, however, to place the blast-furnaces in the localities where ore is raised, and the works for finishing the iron at the centers of the production of the fuel. It is found more economical to carry over the same distance a ton of coke and a ton of pig than to carry three tons of ore and flux. This has produced a displacement of the pig-iron industry, which has been transferred in part to the southern part of the Luxembourg province, in the neighborhood of the mines. On the whole, the Belgian iron trade has thus received a fresh advance, in place of declining, as a consequence of the exhaustion of its native ores. In spite of all the disadvantages which weigh on the country, the care given to every detail, and the application of strict economy even in the smallest points, have preserved to Belgium her place in the metallurgic world, and enabled her to contend successfully against the most powerful competitors. A few figures will be enough to show the progress which has taken place. It is known that the low hearths formerly in use produced in 1546 about 300 kilograms of iron—6 cwt.—in twenty-four hours. At the end of the sixteenth century, the blast-furnace then in use produced about three tons per day. At the end of the eighteenth century, it remained almost the same. A furnace at Chimay produced about 720 tons per annum. For any very great advance upon this, we must go forward to the coke-furnace erected at Seraing by John Cockerill in 1823. This furnace produced about 10 tons in the twenty-four hours. About 1840, furnaces of a new type, erected about the same time in the Cockerill Works and in those of Espérance and of Grivegnée, regularly produced 14 tons of foundry pig or 20 tons of refinery pig per day. In 1848, 24 tons were considered a good average make per day; and in 1860, the Grivégnée furnaces, which gave the best results in production, did not run more than than 9000 tons of pig per annum, or about 25 tons per day. The make has now very largely increased. The Seraing furnaces produce from 65 to 68 tons of Bessemer pig per day, while at Ougrée, two furnaces produced altogether in 1882 more than 41,000 tons. In making pig-iron for ordinary puddling, a make of more than 90 tons per day has been attained. The blast-furnaces at Esch, on the Alzette, in the Grand-Duchy of Luxembourg, produce as much as 110 tons per day. As to wrought-iron, it is difficult to give exact figures. The skill of the workman is a main element in the quantity produced; and the improvements effected by the substitution of coal for wood have had a large influence on the price, without greatly changing the capacity of production. The attempts to puddle by machinery have had little success, and progress has been realized chiefly in the economy of fuel by means of gas-furnaces, especially the Bicheroux furnace. Whereas formerly about one ton of coal was required for every ton of puddled bar produced, 550 kilograms (11 cwt.) are now sufficient. As regards steel, we shall only consider the steel produced by the converter process. The first Bessemer converters, erected at Seraing in 1863, gave from 10 to 12 tons of steel per day. At present, each pair of converters may be reckoned on to give from 150 to 160 tons in the twenty-four hours; and on the new American system, 340 and even 360 tons have been obtained. As a matter of statistics, the annual production of the works in the province of Liége was estimated in 1829 at 7078 tons of pig-iron, 660 tons of castings, 5011 tons of wrought-iron, and 4778 tons of iron manufactured for various purposes. The manufacturing works employed 711 workmen. In 1850, the make of pig-iron had risen to 65,393 tons, that of castings to 7688 tons, that of wrought-iron to 28,252 tons, and, lastly, that of manufactured iron to 7093 tons. In 1882, we find that the province of Liége contained 13 blast-furnaces actually in blast, and employing 1215 workmen. The make of pig-iron was 238,968 tons. The production of wrought-iron and manufactured iron was 126,461 tons, and occupied 5180 workmen. Lastly, the steel-works contained 9 converters, produced 171,937 tons, and occupied 2747 workmen. The average wages of the workmen employed at the blast-furnace is 3 francs per day; those employed at works for making or for working up wrought-iron get an average of 3·46 francs per day; while those employed at the steel-works, properly so called, have on an average 3·58 francs per day. These works, on the whole, have been actuated by 478 engines of various kinds, giving a total of 14,688 horse-power.

CHEAP COAL.

There is hardly an important industry in the cost sheets of which fuel does not constitute an important item, directly and indirectly. During periods of depression like the one through which we are now struggling, every factor is closely scanned by the producer, adversity teaching many methods of economy which prosperity slighted. Improved construction of boiler furnaces and the highest class of modern engines are carefully studied with the view of carrying down the coal bills. Consumers have become very close buyers, and many of them have frequent occasion to rejoice over their success in getting cheap supplies of fuel. Undoubtedly, low figures often tempt them to disregard true economy and sacrifice quality to quantity; but on the whole, there are many evidences that consumers have learnt a good deal during the past year which they are not likely to forget. The question frequently comes up whether it is or is not probable that the benefits of cheap bituminous coal, which consumers throughout the country are now enjoying, are likely to outlast the present period of dullness.

A comparison of the quotations of bituminous coal from a variety of sources in the leading markets will show what point we have reached, and will form the basis upon which a further discussion may take place:

The principal causes of the low figures quoted above are a very great increase in the output and capacity of our mines, a very rapid extension of the railroad system directly tributary to the coal traffic and indirectly affording it increased facilities to leading points; and a general scaling down of wages. Taking up these points in their order, so far as they affect not alone an absolute but also a relative decline in the prices of bituminous coal, we may first note the evidences of a striking growth in the output and capacity of the mines. As to their production, we need only point to the eloquent fact that our mines yielded about fifty-eight million tons of bituminous coal in 1882. We have not, unfortunately, comparative figures on the growth of the capacity of the same mines; but the very fact that the mines were busy during the census year, while, generally speaking, they were working only three-quarter time or less last year, proves that in all likelihood their capacity has grown in even a much greater ratio. Competition, not alone among the producers of our region, but also among regions which have only of late come into conflict, will therefore tend to keep prices low, as no scarcity need be feared.

The extension of our railroad system during the past few years has been phenomenal, and, save the development of the system opening out the Western agricultural regions, the railroads distinctively called "coal roads" have multiplied more than any other. Coal is recognized among railroad managers as one of the best-paying classes of freight, and aside from this fact, the tempting opportunities for the acquirement of wealth by individuals having close relations with the railroads may have contributed much toward stimulating this class of enterprise. Pennsylvania has seen the starting of the Vanderbilt lines southward, through almost a continuous belt of coal territory. A number of rival lines are approaching to tap the Clearfield region; the Rochester & Pittsburg has begun shipments from new territory; the Pennsylvania, Baltimore & Ohio, and Vanderbilt roads are struggling for supremacy in the Connellsville coke district; and a number of minor enterprises are opening out smaller fields. In Virginia and West Virginia, the Chesapeake & Ohio, the Pittsburg & West Virginia Central, and the Norfolk & Western have entered districts in which great mineral treasures lie dormant. In Alabama and Tennessee, coal mining has had a strong and undoubtedly lasting impetus. In Ohio, Indiana, Illinois, and other Western States competitive lines are multiplying, and in the far West the building of a large number of new roads has fairly started an industry that is capable of great development. Almost as great an influence upon the prices of coal and the variety of sources available to the markets has been exercised by the building of railroads not primarily intended to develop coal territory. It has created and fostered a competition which has not only run down freight rates, but has also placed a formidable rival to interior and ocean navigation. A survey of the situation, cursory though it may be, will, we believe, convince the unbiased observer that there is no probability of a heavy increase in the cost of carriage.
